Arch support, D Livingston	[illegible]
Astronomical apparatus, J C Moore	[illegible]
Autographic register, H J Barker	[illegible]
Ax, E Amstut	[illegible]
Axle nut locking device, T W Claudio	[illegible]
Axle skein, H D Hammonning	[illegible]
Ball mill, P T Lindhard	[illegible]
Bath tub leg, W H Lee	[illegible]
Battery, W Gardiner	[illegible]
Battery case, steam storage, F L O Wadsworth	938,446
Bearing, L. C. Trout	937,974
Bearing, antifriction, C. A. Latham	937,884
Bearing, ball, C F Jenkins	937,871
Beater and mixer, F L Bean	938,407
Bedstead, metal, W. A. Wylie	938,405
Beet digger and topper, W. C. Mauer	[illegible]
Beet digger and puller, W. F. Elkis	[illegible]
Belt fastening device, J. E. Golden	938,039
Bicycle handle bar, J B Logan	938,225
Bicycle loading attachment, C A Mason	937,888
Billet heating furnace, C J F Johnson	938,424
Binder, loose sheet book, R Jay	938,057
Binocular, Martin & Stiege	937,884
Blanks, machine for the formation of, D. J Regan	938,116
Block signal system, Nix & Dalgarn	938,331
Board. See Game board.	
Boiler alarm, F C McAdam	937,948
Boiler furnace, steam, F Wagner	937,820
Boiler furnace steam, F A Shoemaker	938,082
Boiler tube cleaner, J D. Thompson	938,089
Book, car record, A J Camp	937 926
Book leaves, reinforcement for, F H Crump	938,070
Book mark, line guide and pencil holder combined, M E Smoot	938,095
Bottle capping machine head, L. C. Krummel	938,225
Bottle non-refillable, H. W Deutsch	938,308, 938,413
Bottling machine liquid, F W Jacob	938,140
Brake head adjustable, W H Fowler Jr	937,980
Brick, facing, J N McQuern	938,430
Brick setting frame, R. C. Penfield	937,938
Brick vitrified paving, K Langenbeck	937,[illegible]
Brush, F W Riehl	938,375
Brush, cloth steaming, Svoboda & Kopecky	938,089
Brush, fountain paint, O Anderson	938,362
Bucket collapsible, D M. Orcutt	938,431
Building construction, H. D. Martin	938,388
Building mold, D. M. Eddy	937,781
Burner attachment, F J Farr	937 989
Button making machine, A. C. Jones	938,180
Cable hauling apparatus, F Shaw	938,174
Cable thimble, O. H. Streblow	938,098
Calking tool, right and left, A. Serfoss	938,178
Camphene, preparation of, O L A Dubosc	937,989
Can testing machine, C. H. McDonald	938,168
Car brake, Rote & Shee	938,340
Car coupling, S. W Wright	938,104
Car coupling operating mechanism automatic, M B Turney, reissue	13,030
Car door, F X Maloney	938,427
Car door hanger freight, A. O Banks	937 751
Car fender, Bruce & Coutts	938,309
Car mover, W McLeish	938,328
Car, passenger railway, J H. B. Brunson	938,037
Car pipe line coupling, P A Seneral	937,874
Car rack, P N Landlue	938,152
Car sand box, D. B Keeports	937,813
Cars, traveling ladder for sleeping, S. M Niblack	938,016
Carbureter, M F Mieville	938,011
Carousel, A J Smith	938,281
Carousel power mechanism, H B Auchy	937 760
Carpet end binder, aisle, H. Posson	938,170
Carpet molding, Rodgers & Schwartz	938 077
Cart and wagon bodies, wear strip for, J T Hamilton	938,230
Cart, dump, L. H & A Young	938,198
Castings by air pressure, means for making, O J Sayers	937 994
Catch, holdfast spring, T Morris	938,297
Catch, safety, A J Thurstans	938,090
Cattle guard, C L Wilcox	938,082
Chain wrench, C E Bonner	937 917
Chair attachment, F Schulz	938,172
Charm and trimming, R S Goddard	937 952
Cheese cutting apparatus, L J Kusick	938,065
Chuck, S. T Lewis	938,490
Cigar lighter electric, S. A Campbell	938,368
Circuit breaker automatic, J N Kelman	938,324
Circuit closing and breaking device for electrically operated annunciators, etc, A May	938,394
Clamp, F J Christman	937 766
Clasp, L. S Murdock	937 841
Cleaning device, G B Hakins	938,421
Clothes line fastener, A Bertram	938 110
Clothes line reel and stretcher, M. Kerrigan	938 398
Clothes pin, reinforced, G Langgons	937 828
Clothes wringer, Walther & Scherer	938,358
Clutch and governor combined, F E Parker	937 861
Clutch frictional, W H Haggard	938,317
Coaster and bottle opener, H. A Parker	937 850
Cock stop and waste, W H Smith	938,442
Colter, plow, W J Winder	938,087
Column clamp, A H Schwerd Jr	938 744
Comb, R. Caldwell	938,040
Combing machine feeding device, Heilman, J C. A Wenning	938,180
Composing machine record strip, Bancroft & Indahl	938,286
Composition of matter, Rowe & Howard	937 869
Computing device, J S Dinkelspiel	938,222
Concrete building making machine, A S. Merriett	938,010
Concrete for the construction of fireproof buildings, fiber, G Rosenleaf	937,808
Concrete post, reinforced, F J Haas	937 794
Condiment holder, A Hitt	937 985
Confectioners' melting table, G F Dickson	938,414
Container closure, H N Norton	937,847
Converter starting device, vapor, P H Thomas	937,971
Cooking cabinet and heat conservator, E P Carpenter	938,121
Cooler. See Milk cooler.	
Copper from raw unroasted ores and other products, extraction of, G Schneider	937 965
Copying machine cutting device, Seden & Bodet	938,199
Corn husking machine, M G Harvey	938,233
Corn tester, seed, G H. Twamley, reissue	13,031
Corner staying machine, W F Morse	937 840
Corset, K V Tojetti	938,358
Cotton gin, E. L. Peterson	937,[illegible]
Cotton gin, W D Deeman	938,324
Couch, A H. Keller	938,344
Crate, collapsible, Smith & Cosgrove	937,880
Crate collapsible, Cosgrove & Smith	938,041
Crate, folding, S W Banks, Jr	937 918
Cream separator, K O. A Carlsson	937 988
Creel and kit combined, Wakefield & Harter	938,233
Crib or bed, folding, B Gundelach	938,318
Cultivator, F E. & J S. Bradley	937,780
Cultivator adjustable tool joint, W H Dausha	937,778
Cultivator, automatic adjustable, W L. Logan	938,191
Culvert metal, Bickelstrel & Ballard	937,870
Curtain bracket, J D. Sullivan	938,088
Curtain fastener, Johnson & Colton	937,888
Cuspidor, McDermott & Story	937 848
Cycle support, A Linde et al	938,065
Davit for hoisting and lowering boats, A Welin	938,447, 938,448
Delivery apparatus, R. T von Knopke	938 [illegible]
Detergent, J Pearson	938,383
Detonator electric, G A Allen	938,318
Die for pressing wheels and like shapes, A. K Andrews	937 [illegible]
Dining table, self waiting, L. R. Johnston	938,342
Dish washer, M L Crouch	937 [illegible]
Dish washer, G. A Lotts	938,[illegible]
Dish washing machine, A M Hanberg	937,[illegible]
Display rack and storage frame, R. B. Baker	938,302
Door and window pattern, A. W Koerner	937,816
Door closure, K. W Gale	938 046
Door construction, sliding, H. K. Heaney	937,810
Door hanger, F J, A Misty	938,284
Door operating mechanism, H. Rowntree	937 870
Door operating mechanism, G. Menasian	938,[illegible]
[illegible]	[illegible]
[illegible], W [illegible]	[illegible]
Drill [illegible], L. T. [illegible]	[illegible]
Drill [illegible], J. Van [illegible]	[illegible]
Drill [illegible], etc., covering for, [illegible]	[illegible]
Draw bar and draft attachment, W. Huber	[illegible]
Dredging bucket, J B. Richards	[illegible]
Drilling attachment for various classes of machines, F. R. Bocorowski	938,118
Dynamos and motors, means for holding in place laminations of alternating current, C. E Wiley	[illegible]
Egg beater, M. D. Christie	[illegible]
Egg case fastening, J. G Dutschke	[illegible]
Electric alarm, E. C. Bronson	[illegible]
Electric attachment plug, S. W. Ito	[illegible]
Electric furnace, A. C. Higgins, reissue	[illegible]
Electric heater, H. W Dunhard	[illegible]
Electric protection system, C. Jacobsen	[illegible]
Electric wiring protecting box, H. W King	[illegible]
Electrical devices, strain relief for, G. W. Goodridge	938,119
Electrodes, making active material for storage battery, J W Aylsworth	[illegible]
Electrolytic apparatus, A. Reichaux	[illegible]
Elevator, D C Hughes	[illegible]
Elevator, J S. Mackie	[illegible]
Embroidery punching tool, M. N Jarvis	[illegible]
Engine electric igniter, gas, J A. Charter	[illegible]
Engine reversing mechanism, traction, J D. Musser	938,164
Engine starting crank, internal combustion, J A. Lawson	[illegible]
Evener, W A Paul	[illegible]
Excavating machine, M. G Hassell	[illegible]
Exerciser, F P Fay	[illegible]
Exercising apparatus, W P Stell	[illegible]
Exercising apparatus, electrical, W C. Shauber	[illegible]
Exercising machine, L. S. Hackney	[illegible]
Exhibition apparatus, B. C. Adams	[illegible]
Explosion engine, F H Trent	[illegible]
Eyeglass chain reel, O. B Wedell	[illegible]
Fabrics and other materials, apparatus for impregnating, B. W Strohm	[illegible]
Fastening, H. E Percival	938,078
Feed box and driver's back rest, combination, J J Moriarty	[illegible]
Feed water heater, H. Etheridge	938,184
Feeder, poultry, J R. Ryan	[illegible]
Feeding and watering device, A. C. Marsom	937,947
Fence machine wire, J W, P. W, and W H Sommer	[illegible]
Fence post mold, P J Haas	[illegible]
Fence post or stay, P Arendt	[illegible]
Fender. See Vehicle fender.	
Filtering and washing the filtered material, apparatus for, Grothe & Carter	938,078
Filtering apparatus, C. W Schultze	[illegible]
Fire box, W D. Boyce	[illegible]
Flag or signal, G W Dallimore	[illegible]
Float ball and float valve connection, A B. Noonan	938,071
Flue, sectional, S. B. Goucher	938,140
Flush tank, B. Walker Jr	[illegible]
Flushing apparatus, B Opperman	938,019
Flushing apparatus, C. A Wulf	[illegible]
Forge and furnace, W N Best	938,111
Form gage, E. R. Heatone	[illegible]
Freezing plate, E. H Kirk	[illegible]
Frost overcoming means, Hardinge & Pagel	[illegible]
Fruit gatherer, C. G Hannah	937,797
Fruit package, J A Hilliker	[illegible]
Fruit picker, C Virgin	[illegible]
Furnace charging apparatus, blast, F H Crockard	938,411
Furnace grate operating mechanism, H Bevan	938,112
Game board, R. A Hallock	937,796
Game board, C Tauron	938,180
Garbage receptacle, M Cullen	937,772
Garment rack, B. Harshkowitch	[illegible]
Gas air heater, F S. Lamson	[illegible]
Gas burner, T S Philpott	938,029
Gas burner, F T. Todd	[illegible]
Gas burner, A Hoffman	[illegible]
Gas fixture safety connection, D. Tangney	937,891
Gate, W B Homer	937,997
Gear cutting machine, T C Dill	938,304
Gears, adjustable device for yieldingly holding beveled, R J Loring	937,982
Gearing, power transmission and reversing, Crane & King	937 771
Gearing reversing, W. A. Slusher	937,878
Glass beveling machine or apparatus, W O. Bailey	937,812
Glass drawing apparatus, automatic air valve mechanism for, H Doerhamp	[illegible]
Glass, making wire, C J Jungers	[illegible]
Governor, bench, A. S. E. Little	[illegible]
Governor, engine, S. S. Hall	937 868
Grain hulls, apparatus for removing, G E. Henry	[illegible]
Grate shaker, W J Simpson	[illegible]
Grave filling apparatus, D A. Sparks	[illegible]
Grinder for cutter bars, G. R. Hudson	[illegible]
Grinding device interior, J R. Koller	[illegible]
Grinding machine, saw tooth, W H Lucas	[illegible]
Grinding mill, F Nolte	[illegible]
Grooving machine cutter head, H R Ross	[illegible]
Guns and rifles, magazine lock for take down repeating shot, F Hardy	937,984
Hair growing device, Daggett & Hingshart	938,125
Hammer, P H Bartsch	937,815
Hammer nail holding attachment, P Carlsson	[illegible]
Hammer or the like, drop, E. Holmgren	[illegible]
Harrow, R. D. Orton	[illegible]
Harrow and weeder, combined, J O. Richmond	[illegible]
Harvester, beet, F C. Harding	[illegible]
Harvester, corn, R. M. Reed	[illegible]
Hasp fastener, O Lovely	[illegible]
Hat frame machine, Hoppe & Becker	[illegible]
Hat guard, O. H. Shaw	[illegible]
Hat pin, J M. Savit	[illegible]
Hat sweat band, N E. Marshman	[illegible]
Hay carrier, J Ney	[illegible]
Hay press, automatic, A. C. Laughlin	[illegible]
Hay rake and stacker combined, C. A. Robbins	[illegible]
Hay tedder, A Dobey	[illegible]
Heater, W G. Glenn	[illegible]
Heating apparatus, H. E. Smith	[illegible]
Hinge, gate, A. Higgins	[illegible]
Hitching device, detachable, W Hassard	[illegible]
Hoe, O T. Cuppet	[illegible]
Horizontal boiler, R. A Beyl	[illegible]
Horn support, E. Manneck	[illegible]
Horseshoe calk, A C Schneider	[illegible]
Hose and pipe coupling, F. March	[illegible]
Hose coupling, F Vlach	[illegible]
Hose coupling, J M Towne	[illegible]
Hose coupling and turn plug, T A. Arther	[illegible]
Hub fastener, T J Cupsted	[illegible]
Hydrant stand pipe, and the like, H. E. Lange	938,064
Hydraulic machine for making casing, J B. French	[illegible]
Hydrocarbon mixer, W C. Paul	[illegible]
Ice making appliance, C C Madson	[illegible]
Impression apparatus, L. Huffman	[illegible]
Incubator, C R. Adair	[illegible]
Incubator, R A Maisch	[illegible]
Incubator automatic heat regulating, W W Wetheris	[illegible]
Incubator, metallic, F C. Perkins	[illegible]
Indicator. See Test indicator.	
Insulator bracket, R. V Brown	937,866
Insulator for electric lines, strain, E. M. Rose	[illegible]
Insulator strain, Varney & Rose	[illegible]
Insulator, strain, T Varney	937,857, [illegible]
Insulator strain, C L. Boldman	[illegible]
Internal combustion engine, J. V Rice, Jr	[illegible]
Ions, process and apparatus for the production of, L. L. Blake	[illegible]
Iron, J Marchak	[illegible]
Ironing board shirt holding mechanism, E. W Fowler	[illegible]
Irrigating device, N E. Austin	[illegible]
Jar opener, J R Smith	[illegible]
Jaw tool pivoted, G. W. Sewell	[illegible]
Jewelry safety catch, J W [illegible]	[illegible]
[illegible], A. L. [illegible]	[illegible]
[illegible], A. A. [illegible]	[illegible]
[illegible]	[illegible]

[illegible] and [illegible], J. H. Wils[illegible]	[illegible]
[illegible] holder, [illegible]	[illegible]
[illegible] shade, art, [illegible]	938,038
[illegible] socket and automatic [illegible], J. W. [illegible]	937,988
Lamp socket, fastening, electric, H. Christensen	938,212
Lamp socket, incandescent, H. A. [illegible]	938,038
Lamp socket retainer, electric, H. Christensen	938,213
Lantern, J. O. Alwood	937,748
Lap-forming mechanism, C. B. T. Scribner	938,457
Last, T. Ammelius	937,986
Lathe head stock, White & Medford	938,080
Lathe tool, A. Stevenson	937,895
Lathe, turret, C. L. Libby	938,156
Lathes, planers, etc., tool for, W. R. Delano	937,778
Lavatories, etc., leg attachment for, W. H. Lowe	938,157
Leather splitting machine, J. Benfield	937,765
Lens grinding implement, F. Burkhop	937,763
Light extinguisher, automatic, H. E. Matthai	937,896
Lightning rod, J. F. Goots	938,137
Liquid concentrating apparatus, O. Venter	937,976
Loading machine, grain, B. F. Kepner	937,914
Lock, J. F. Beatty	937,750
Lock, H. O. Voight	938,444
Locomotive boiler, E. A. Reeve	938,171
Logging swivel joint, J. V. Robinson	937,960
Loom shuttle or filling carrier, O. A. Sawyer	937,963
Loom warp stop motion, E. S. Stimpson	937,888
Loom, weft-replenishing, H. Wyman 937,979,	937,980
Loom yarn stripper, weft replenishing, F. W. Moore	937,938
Looms, weft-controlling mechanism for weaving, J. Rostron	938,276
Lubricator, C. A. Damon	938,415
Lumber loading mechanism, F. Pearson	937,954
Mail chute, L. Ehrlich	938,416
Manicuring device, H. W. Durkee	938,237
Masonry drill, A. Spiess	938,177
Mask, breathing, R. Kuhn	938,247
Match box, B. F. Hewlett	937,869
Mercury circulating device, J. Whiting	938,191
Message recording apparatus, F. A. Skelton	938,441
Messenger hanger, C. H. Cook	938,216
Metal cutting shears, J. O. Charpentier	938,128
Metal hoop, J. W. Brainard	938,205
Metal working machine, automatic, F. E. Brightman	937,762
Metals, melting, W. Griffith	938,377
Milk cooler, W. T. Murray	937,936
Milking apparatus, E. E. Good	937,759
Milling process, M. C. Peters	938,331
Miter box, N. P. Lithander	937,946
Miter box, W. E. Smith	938,248
Mixing machine, F. Aeschbach	938,301
Molding machine, W. J. Sterling	937,985
Molding machine, H. H. Harris	938,321
Motor control system, electric, J. N. Mahoney	938,160
Mower, lawn, N. Walker	937,977
Mowing machine, G. W. Willis	938,100
Muffler, H. B. Winters	938,101
Music leaf turner, Stragiotti & Vercellini	938,095
Music stand attachment, C. J. Willis	938,400
Musical instrument attachment, H. Gunther	938,142
Necktie fastener and collar button, T. Papworth	937,849
Needle serving box, J. Hermann	938,285
Nippers, M. Friday	938,376
Nut lock, T. Hand	938,320
Occulting light, White & Cornick	938,031
Oil burner, E. K. Hill	938,236
Oil burner, G. W. Moore	938,428
Open hearth furnace, Knox & Murray	938,245
Oranges, machine for washing, A. Taplin	937,970
Ores, apparatus for pulverizing, desulfurizing, or oxidizing metallic and other, Royer Lockenbach	938,006
Ores, chloridizing, C. A. Diehl	938,044
Ores, treating poor sulfid, A. Holdsworth	938,055
Oxygen and nitrogen compounds, process of and apparatus for the production of, Haber & Koenig	938,316
Packing rings, making piston, W. Geiser	938,420
Packing, steam, O. D. H. Bentley	937,916
Pan lifter, H. Walker	938,187
Paper feeding machine, G. B. Maegly	938,008
Paper lunch box, H. J. Zell	938,406
Pencil holder, F. G. Knapp	937,835
Pendant switch, J. G. Peterson	937,857
Pendulum bob, rotary, C. Grivolas	937,792
Penholder, J. Altman	937,747
Penholder, C. F. Seeman	937,873
Penholder, W. T. Nelson	938,130
Phonograph, P. Weber	937,905
Photographic film developing machine, R. A. Taylor	938,297
Piano players, apparatus for producing perforated records for automatic, H. P. Ball	938,452
Picker. See Fruit picker.	
Picture exhibiting apparatus, moving, Dyer & Holden	937,779
Pie plate lifter or holder, L. C. Lynotte	938,258
Piling, sheet, W. A. Kriedler 937,817,	937,818
Pillow sham holder, M. A. Nally	938,015
Pipe coupling, M. F. Kelly	938,128
Pipe main service connection, W. N. Phillips	937,958
Pipe section mold, curved, W. S. Sigler	938,084
Pipe threads and like work, machine for chasing, W. T. Johnston	938,058
Pipe wrench, J. R. Richards	937,959
Pipes, transporting bar for, W. S. Sigler	938,023
Pipes, machine for making continuous, R. F. Dockery	938,223
Planetarium, F. J. & W. F. Trippensee	937,869
Planter marking attachment, corn, L. P. Lewis	938,399
Plastic material into charges, machine for dividing, G. E. Gowdy	938,051
Plastic material machine for dividing, G. E. Gowdy	938,050
Plastic materials, nested dies for forming bodies from, P. J. Fish, Sr	938,047
Plate holder, L. M. Siegel	938,082
Plunger mechanism for jig tanks, G. H. Elmore	938,307
Potato hook rake attachment, C. Kropp	938,001
Powder box cover, G. Messinger	938,161
Power controlling apparatus, W. R. McKeen, Jr	937,844

SENSITIVE LABORATORY BALANCE

By N. Monroe Hopkins. This "built-up" laboratory balance will weigh up to one pound and will turn with a quarter of a postage stamp. The balance can be made by any amateur skilled in the use of tools, and it will work as well as a $125 balance. The article is accompanied by detailed working drawings showing various stages of the work. This article is contained in SCIENTIFIC AMERICAN SUPPLEMENT, No. 1184. Price 10 cents. For sale by MUNN & Co. Inc. 361 Broadway, New York City or any bookseller or newsdealer

How to Construct An Independent Interrupter

In SCIENTIFIC AMERICAN SUPPLEMENT 1615 A. Frederick Collins describes fully and clearly with the help of good drawings how an independent multiple interrupter may be constructed for a large induction coil.

This article should be read in connection with Mr Collins' article in SCIENTIFIC AMERICAN SUPPLEMENT, 1605, "How to Construct a 100-Mile Wireless Telegraph Outfit."

Each Supplement costs 10 cents; 20 cents for the two. Order from your newsdealer or from

Two Good Books for Steel Workers

Hardening, Tempering, Annealing and Forging of Steel

By JOSEPH V. WOODWORTH

Size 6¼ x 9¼ inches. 288 pages. 201 illustrations. Price $2 50 postpaid

THIS is a practical work treating clearly and concisely modern processes for the heating, annealing, forging, welding, hardening and tempering of steel, making it a book of great value to toolmakers and metal-working mechanics in general. Special directions are given for the successful hardening and tempering of steel tools of all descriptions, including milling cutters, taps, thread dies, reamers, hollow mills, punches and dies and various metal-working tools, shear blades, saws, fine cutlery and other implements of steel, both large and small. The uses to which the leading brands of steel may be adapted are discussed, and their treatment for working under different conditions explained, also special methods for the hardening and tempering of special brands. A chapter on case-hardening is also included.

The American Steel Worker

By E. R. MARKHAM

Size 6¼ x 8 inches. 367 pages. 163 illustrations. Price $2 50 postpaid

THIS is a standard work on selecting, annealing, hardening and tempering all grades of steel, by an acknowledged authority. The author has had twenty-five years' practical experience in steel-working, during which time he has collected much of the material for this book. Careful instructions are given for every detail of every tool. Among the subjects treated are, the selection of steel to meet various requirements; how to tell steel when you see it; reasons for different steels; how to treat steel in the making of small tools, taps, reamers, drills, milling cutters, hardening and tempering dies; pack-hardening; case-hardening; annealing; heating apparatus, mixtures and baths, the best kind, and why; and in fact everything that a steel-worker would want to know is contained in this book.

OUR SPECIAL OFFER: The price of these books is $2.50 each, but when the two volumes are ordered from us at one time, we send them prepaid to any address in the world on receipt of $4.00.

THE 10,000-TON SUCTION DREDGER FOR USE ON THE MERSEY.

(*Continued from page 334.*)

Each valve is of tapered cylindrical form extending the full depth of the hopper with open-bottomed valve at the lower edge, and has a lift of four feet. These valves are worked by hydraulic cylinders controlled from fore-and-aft gangways and supported by a continuous fore-and-aft girder running the full length of and above, the hoppers. Guide rings efficiently stayed to the hopper sides are fitted at the upper and lower parts of the valves for steadying the same.

A surface valve with lever for opening or closing it from the gangways is fitted on top of each hoppor valve to drain off the surface water. During dredging operations the mixture of sand and water is delivered into the landers and thence falls into the hoppers through the valves already described. The sand settles in the hoppers while the surface water escapes aft along the waterway formed by the hopper coamings to the weir plates which can be adjusted to suit the trim of the ship and then flows overboard through large rectangular shoots two of which are disposed on each side. When discharging spoil the hopper valves are raised, and the sand rapidly falls through the openings in the bottom of the vessel.

There is an indicator fitted in the chart room which shows the draft of the ship together with a complete system of repeating telegraphs and speaking tubes for transmitting orders to the pumping and propelling engine rooms and to the different winchmen in their respective winch houses. Moreover there are powerful electric alarm bells fitted to the pipemen's positions. Pushes are provided for each pipeman and one on the navigating bridge so as to give alarm in case of necessity.

The hydraulic installation carried out by the builders of the ship comprises a set of three-cylinder inverted high pressure direct-acting engines having three cranks and three single-acting ram pumps driven direct from the piston rod crossheads. The hydraulic pressure is 800 pounds per square inch and is used for working the four main sluice valves on the suction pipes at the sides of the vessel, as well as those on the delivery pipes at the ends of the landers and for opening and closing the twelve hopper discharge valves.

The propelling machinery is right aft and consists of two sets of inverted vertical, triple-expansion engines of the same type as the pumping engines, each having cylinders of 22¼ inches, 37 inches, and 61 inches diameter respectively by a stroke of 45 inches. Steam is raised in four large single-ended marine boilers measuring 15½ feet by 12½ feet placed between the propelling and pumping engine rooms and constructed for a working pressure of 180 pounds per square inch. Watertight doors controlled from the upper deck are fitted in the machinery space bulkheads to provide access from one room to another.

The side compartments adjacent to the hoppers, as well as the two forward holes, are buoyancy spaces rendered necessary for the vessel to support her weight of hull plant and load on the specified draft of water.

The engineers and officers are housed in the poop and the crew in the forecastle, the master's cabin being placed in a large teak house on the navigating bridge with the chart and wheel house above.

The vessel is fitted throughout with a complete installation of electric light on the incandescent system. The engines and dynamo are placed in the propelling-engine room. The engine is of the inclosed type compound direct double-acting and coupled direct to the dynamo, which is of the direct-current compound wound pattern. The powerful windlasses, each driven by separate vertical engines

Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value, of which over 17,000 are listed in a carefully prepared catalogue, which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical or engineering subject on which special information is desired, some papers will be found in this catalogue, in which it is fully discussed by competent authority.

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS. The article tells how a small and simple experimental installation can be set up at home. Scientific American Supplement 1551.

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME is described in Scientific American Supplement 1566.

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement 1566.

HOW TO MAKE A 100 MILE WIRELESS TELEGRAPH OUTFIT is told by A. Frederick Collins in Scientific American Supplement 1605.

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that any one can make it.

A ¼ H.P. ALTERNATING CURRENT DYNAMO. Scientific American Supplement 1558.

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement 1574.

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX, PINS AND A RUBBER BAND is the subject of an article in Scientific American Supplement 1578.

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement 1582, with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY. In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid, to explain the meaning of capillary elevation and depression, to serve as a hydraulic tourniquet, an aspirator and intermittent siphon, to demonstrate the ascent of liquids in exhaustive tubes, to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement 1583.

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement 1594.

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER. Clear diagrams giving actual dimensions are published. Scientific American Supplement 1615.

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement 1618. A plunge battery of six cells, a two-inch spark induction coil, a pair of one-pint Leyden jars and an inductance coil and all the apparatus required, most of which can be made at home.

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements 1363 and 1381.

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained with the help of diagrams in Scientific American Supplement 1622.

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT, illustrated with diagrams. Scientific American Supplement 1623.

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE, illustrated with diagrams. Scientific American Supplement 1624.

HOW TO MAKE A MAGIC LANTERN. Scientific American Supplement 1546.

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement 1555.

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement 1561.

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained with the help of illustrations in Scientific American Supplement 1573.

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement 1594.

Good articles on SMALL WATER MOTORS are contained in Scientific American Supplement 1494, 1049 and 1406.

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement 1472.

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement 1433.

A SEWING MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement 1210.

A WHEATSTONE BRIDGE. Scientific American Supplement 1595.

Good articles on INDUCTION COILS are contained in Scientific American Supplements 1514, 1522 and 1527. Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement 966.

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement 1527.

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements 1561, 1563 and 1566.

ANEROID BAROMETERS, Scientific American Supplements 1500 and 1554.

A WATER BATH, Scientific American Supplement 1464.

A CHEAP LATHE UPON WHICH MUCH VALUABLE WORK CAN BE DONE forms the subject of an article contained in Scientific American Supplement 1562.

Each number of the Scientific American Supplement costs 10 cents by mail.

Order from your newsdealer or from

MUNN & CO., Inc., 361 Broadway, New York

and connected by compound positive clutches at both crank and main shafts, are fitted on the forecastle head for working the anchors

The steam steering is of the Caldwell combined steam and hand type with control shafting to the steering standard on the navigating bridge and is placed in the engine-room casing Hastie's hand screw steering is fitted aft immediately over the rudder head for use in case the steam gear breaks down On the starboard side a motor launch is carried under Welin bow davits ready for immediate use for taking soundings or making observations

◆

SOME CURIOSITIES OF INVENTION.

(Concluded from page 33?)

by cork bulwarks *b* We wonder if the inventor really believes in the efficacy of the hand-operated screw propeller which he has provided

The Society for the Prevention of Cruelty to Animals would undoubtedly interest itself in restraining the inventor who devised the arrangement here shown to enable a dog or cat to run a sewing machine We once heard of a man who patented a contrivance for driving a coffee mill by means of a bicycle so that by the simple contrivance of riding a bicycle it was possible to obtain not only a certain amount of exhilarating exercise but also to provide enough ground coffee for breakfast This patentee surely outdoes him The dog is made to rotate a central shaft carrying a large gear wheel which meshes with a small bevel gear carried on the sewing machine driving wheel It seems to us that after the dog had sewed one shirt he would be too dizzy to do much more or perhaps when that occurs the central shaft is to be driven in the opposite direction

A grain of common sense is to be found in the trunk that becomes its own luggage trolley for it must be confessed that the ordinary trunk when full is not the easiest thing in the world to handle The inventor has provided a single wheel and a folding lever handle which serves the purpose of pushing the wheeled trunk along He evidently was not concerned much with the problem of the amount of space consumed by the wheels and the handle when folded within the trunk

The handle shown for carrying parcels used in carriages has been employed in European railways The device consists simply of two straps and a rest board with the whole easily detachable Straps serve the purpose of binding the rest board and walking sticks and umbrellas together

A boat driven by windmills is certainly a mechanical curiosity Just why this complicated arrangement of bevel gears connecting the propeller shaft with the vertical windmill shaft should be better than canvas transcends our imagination

There is a touch of the Yankee in the fishing device the last of the inventions illustrated Evidently the inventor was accustomed to fishing in streams where bites were few and far between and where patience was ill rewarded He has contrived a fishing pole with a swinging arm carrying a clapper which is made to ring a bell as soon as a fish bites and swings the arm down

◆

BIRDS OF PASSAGE

(Continued from page 335)

of the return of the same individuals Some wonderful European records of the return of a species to a given nesting site are given by the late Prof Alfred Newton A common falcon *Falco peregrinus* a cosmopolitan bird commonly known as the duck hawk in this country had its eyrie at one point in Finland for 110 years that is to say there was at this same point an occupied nest of this species from 17?6 to 18?5 At Oxbridge in one or the other of two earthen bottles placed for their use a pair of blue titmice had their nest every year with two

STILL GROWING

Over 210,000 Circulation

LESLIE'S WEEKLY is growing in circulation, influence and advertising value—growing fast.

Over 200,000 people subscribe to or buy LESLIE'S WEEKLY each week because they want an illustrated *newspaper* and cannot get anything like it elsewhere.

Advertisers use LESLIE'S WEEKLY because they recognize it as the only paper in its class without a competitor in a highly profitable field.

Because in consequence they run less risk of duplicate circulation than in the multitude of other publications which aside from name are all about alike.

Because a big publication like LESLIE'S WEEKLY filled with the finest photographs depicting every important or nationally interesting event, makes the best possible history of the world's progress and insures each weekly issue a longer life than most monthly magazines enjoy.

Advertisers who buy space now at the rate of 75 cents a line will get the benefit of this large and rapidly increasing circulation which is absolutely guaranteed.

BARKER MOTORS

Reliable.—1½ to 10 H P—Economical

Their perfect operation and reliability are due to common sense mechanical ideas and good construction. While low in price, they are made of best materials with careful attention to details.

C. L. BARKER, NORWALK, CONN.

Just Published—A BOOK OF INTEREST TO RIFLEMEN

The Bullet's Flight from Powder to Target

The Internal and External Ballistics of Small Arms. A Study of Rifle Shooting with the Personal Element Excluded, Disclosing the Cause of the Error at the Target,

Illustrated with one hundred and eighty-eight plates, showing the results of over three hundred rifle experiments performed and chronologically arranged

By F. W. MANN, B.S., M.D.

Size 7½ x 9¾ inches. 384 Pages. Price $4 00 postpaid

THIS is a thoroughly practical treatise and deals with a subject the literature of which is not commensurate with its importance or interest, and it possesses unusual value, not only because it furnishes a large amount of information, of a very practical kind, but because this information is the result of a practical experience on the part of the author, extending over a period of thirty-eight years. The results of the author's experiments, as here given, have been persistently and laboriously worked out with an earnest desire to assist his fellow marksmen. In view of the fact that conjecturing and theorizing have been so prevalent in rifle literature, the work has been kept free from speculation, except where they have either been proved to be false or have been fully substantiated by recorded experiments. Most of the illustrations are photographic reproductions of the results of actual tests. Every page is full of interest for the rifle enthusiast. There is a full discussion of various kinds of rifles, of the effect of differences of length, of variations of rifling, etc., as well as of [illegible] experiments such as that of venting the barrel near the muzzle. An idea of the contents may be gathered from a few of the subjects treated such as the Personal Element vs. Mechanical Rifle Shooting; Utility of Vented Barrels; High-Pressure Sharpshooting Powder; Telescope Mounts; Rusted Rifle Bores vs. Smokeless Powder vs. Primers; Accurate Ammunition Difficulties Flight of Bullets; Gyration and Oscillation; Motions Executed by Normal Flying Bullets; Determining Rifle Twists; Kinetics of Spin, etc. In many respects this work is unique in the literature that has been published on this subject. It is a thoroughly practical work and will be found to be of very real value to those who are engaged in a study of the ballistics of the rifle with a view of improving the all-around efficiency of that weapon.

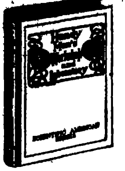
THREE NEW BOOKS JUST PUBLISHED BY MUNN & CO.



HANDY MAN'S WORKSHOP AND LABORATORY

COMPILED AND EDITED BY

A. RUSSELL BOND

12mo. 467 Pages. 370 Illustrations. $2.00 Postpaid

EVERY practical mechanic, whether amateur or professional, has been confronted many times with unexpected situations calling for the exercise of considerable ingenuity Some time ago it was decided to open a department in the Scientific American devoted to the interests of the "Handy Man." There was an immediate response from amateur and professional mechanics all over the country who sent in thousands of suggestions. The best of these have been prepared for use in the present book and a large portion of them has never before been published. It may be regarded as the best collection of ideas by resourceful men. Not only amateur mechanics, but professional men as well will find in this book hundreds of ingenious ideas, wrinkles or "kinks," as they are called. The electrician, the physicist and the chemist have all furnished their quota of ideas.

BRIEF TABLE OF CONTENTS

Chapter I —Fitting up a workshop.—Building the shop, the work bench, the tool grinder, the lathe, the scroll saw, the drill press, etc

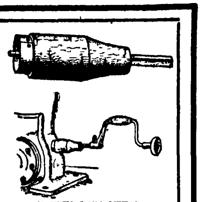
Chapter II.—Shop "kinks."—Thread cutting without a die, how to coil a spring, substitutes for a pipe wrench methods of driving a nail, drills and methods of drilling, sawing holes in metal, home-made micrometer, turning a ball, etc

Chapter III.—Soldering of metals and the preparation of solder and soldering agents.

Chapter IV —Handy man in the factory —Emergency uses of the lathe, milling machine, etc.

Chapter V —Handy man's experimental laboratory —Home-made laboratory apparatus, elastic pendulum, chemical experiments, home made seismograph, etc.

Chapter VI.—Handy man's electrical laboratory —Static electric apparatus and experiments, storage and dry batteries, home-built motors, an electrolytic rectifier, wireless telegraphy etc.

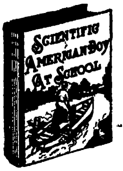


HOW TO DRILL METAL

Chapter VII —Handy man about the house —Decorations and ornaments, electrical fireless cooker iceless refrigeration, milk testing without apparatus home made vacuum cleaner how to mend garden hose, etc.

Chapter VIII.—The handy sportsman —Portable automobile house converting a buggy into an automobile auto repairs, a one man airship a Chanute type glider ice yachts, scooters, installing a motor in a boat bicycle coasting sled, reducing the range of a rifle.

Chapter IX —Model toy flying machines. Monoplanes, biplanes, an aeroplane kite Diabolo flying machine, etc

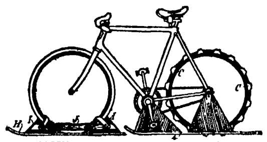


SCIENTIFIC AMERICAN BOY AT SCHOOL

BY A. RUSSELL BOND

12mo. 338 Pages. 314 Illustrations. $2 00 Postpaid

THE present volume is a sequel to "THE SCIENTIFIC AMERICAN BOY," of which many thousands have been sold, and it continues the narrative and describes the construction of various devices and apparatus with particular reference to outdoor use. The constructions are fully within the powers of the average boy and the text is written so clearly that there can be no failure if attention is paid to detail. The list of chapters below gives an admirable epitome of the contents.



ANY BOY CAN CONVERT HIS OLD BICYCLE INTO A BICYCLE SLED

BRIEF TABLE OF CONTENTS

Chapter I.—Initiation.

Chapter II —Building a dam.

Chapter III —Boat building.—The construction of a bateau.

Chapter IV —The club house on the lake.—How to chop down a tree, constructing a platform in the lake, building a lake house.

Chapter V —A chapter of surprises.

Chapter VI —The Modern Order of Ancient Engineers.—The pantagraph, the work bench, an Egyptian lathe, bow drill, twisted cord drill.

Chapter VII.—A pedal-paddle boat.—A boat fitted with paddles driven by a bicycle.

Chapter VIII.—Surveying the Lake.—An underwater stockade, surveying with the thumb, with a ruler, with a pin, with a 2-foot rule, measuring heights by shadows and by reflection, plane table surveying, intersection and traversing

Chapter IX.—Sounding the lake.—Method of taking and recording the soundings, a camera as a telescope, making a telescope

Chapter X.—Signaling systems.—The ball, cone, and drum code, the semaphore system, night semaphore and electric signals, the cipher disk

Chapter XI —The Howe truss bridge.—A plank bridge, construction of the Howe truss, the snowball catapult.

Chapter XII.—The seismograph.—Construction of a simple instrument for recording earthquakes.

Chapter XIII A canal lock.—Inclined elevators, construction of a lock for small boats, construction of a drawbridge.

Chapter XIV —Hunting with a camera.—An electric shutter, the umbrella blind, climbers, under water photography

Chapter XV —The gliding machine

Chapter XVI —Camping ideas.—Sleeping bags, pine beds, fireless cookers, iceless refrigeration, water proof matches.

Chapter XVII —The haunted house.

Chapter XVIII.—Sun dials and clepsydras.—Square faced dial, vertical dial water clock

Chapter XIX.—Fish tail propeller —A new form of propeller for small boats.

Chapter XX.—Kite photography —Triggers for springing the camera shutter telephone kite signals.

Chapter XXI —Water kites and current sailing A removable keel, sailing with a drag

Chapter XXII —A canvas-covered wooden canoe.—Steam box for bending the ribs.

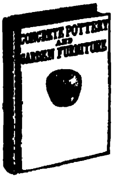
Chapter XXIII —The bicycle sled.

Chapter XXIV —Magic.—An Egyptian entertainment sleight-of hand tricks.

Chapter XXV —The sail boat.—Construction of a small sloop, leeboards

Chapter XXVI —Water sports.—Dredging a swimming hole, outdoor gymnasium, swimming sail, human fish, sea serpent

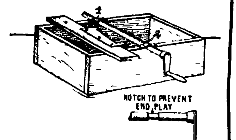
Chapter XXVII —The geyser fountain.—A siphon fountain, concrete basin



CONCRETE POTTERY AND GARDEN FURNITURE

BY RALPH C. DAVISON

16mo. 196 Pages. 140 Illustrations. $1.50 Postpaid



BOX FOR TURNING PLASTER

THIS work should appeal strongly to all of those interested in ornamental concrete as the author has taken up and explained in detail in a most practical manner the various methods of casting concrete into ornamental shapes. The titles of the thirteen chapters of which the book is composed will give a general idea of the broad character of the work. The first two chapters explain a most unique and original method of working pottery which has been developed by the author. They are entitled

I. Making Wire Forms or Frames. II Covering the Wire Frames and Modeling the Cement Mortar into Form. The remaining eleven chapters are as follows III Plaster Molds for Simple Forms. IV Plaster Molds for Objects Having Curved Outlines. V Combination of Casting and Modeling—An Egyptian Vase. VI Glue Molds. VII Colored Cements and Methods Used for Producing Designs with Same. VIII. Selection of Aggregates. IX. Wooden Molds—Ornamental Flower Pots Modeled by Hand and Inlaid with Colored Tile X Concrete Pedestals XI. Concrete Benches. XII. Concrete Fences. XIII. Miscellaneous, including Tools, Waterproofing and Reinforcing. The chapter on color work alone is worth many times the cost of the book inasmuch as there is little known on this subject, and there is a large growing demand for this class of work The author has taken for granted that the reader knows nothing whatever about the material, and has explained each progressive step in the various operations throughout in detail. These directions have been supplemented with half-tones and line illustrations which are so clear that no one can misunderstand them.

BUSINESS OPPORTUNITIES

A RARE OPPORTUNITY presents itself for a high class salesman to handle an article of utility needed on every street, in every house and store as well as halls and churches. Substantial commissions or straight purchase plan. Standard Chicago, 8 W. Michigan St., Chicago.

Inquiry No. 8868.—Wanted to buy nickeloid for buttons.

IF YOU WISH TO BUY OR SELL COINS send stamp and ask Mr. Alexander for information and a free copy of valuable illustrated pamphlet. Alexander & Co., 33 Devonshire St. Boston, Mass. (Established 1872.)

Inquiry No. 8880.—For the address of the Windsor Mfg. Co., manufacturers of waterproof collars and cuffs.

AGENTS: IF I KNEW YOUR NAME, I would send you our $2.50 sample outfit free this very minute. Let me start you in a profitable business. You do not need one cent of capital. Experience unnecessary. 50 per cent. profit. Credit given. Premiums. Freight paid. Chance to win $500 in gold extra. Write me for free outfit. Jay Black Pres. 40 Beverly St., Boston Mass.

Inquiry No. 8918.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

PATENTS FOR SALE

FOR SALE on a royalty basis a Bundle Tying Machine for mercantile use. A new field of enormous possibilities. Cheap in comparison with its need. Address J. W. Hall, Wrightstown, Pa.

Inquiry No. 8922.—Wanted the address of Worthington Boiler Co.

FOR SALE—Patent No. 927,774. A new and useful Button Fastener for fastening buttons without sewing. Fills a long felt want. Will be a good money maker. Sell outright. Anton Micklah, Market Lake, Idaho.

Inquiry No. 8966.—Wanted the address of the Cohendet Motor Co.

FOR SALE—Patent No. 933,561. The most useful automobile appliance known. No auto stalled that has this appliance. Address H. S. Delamere, Room 1 South Berkeley Bank Building, Berkeley, Cal.

Inquiry No. 8987.—Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

FOR SALE.—Patent No. 937,141. Improvements on airships and aeroplanes. For further information write to A. E. G. Lubke, 853 Clayton Street, San Francisco, Cal.

Inquiry No. 8990.—For information regarding shoes not made of leather but similar to the same and are as durable.

OUTRIGHT SALE OR ON ROYALTY. U. S. Patent No. 935,037. Canadian Patent No. 118,362. An apparatus for producing uniform fluid pressure for engines. A great saving in expense. For further information write Elmer Engebretson, Devils Lake, North Dakota.

Inquiry No. 8996.—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE

FOR SALE CHEAP. One Potter trestle trench machine; one surface Potter trench machine; two Lambert 20 H. P. hoisting engines; one Buffalo concrete mixer; one centrifugal pump; one Edison band pump; one steam pump; a lot of screw jacks and braces; steel sheet piling 16 feet by 7 inches for 100 feet complete sewer and all tools necessary for sewer work. Address Rich Construction Co., 507 Missouri Trust Building, St. Louis, Mo.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

FOR SALE.—Engine lathe swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads 4 to 40 in. Price only $45.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9010.—Wanted to buy a "Rector Help-a-Phone."

TYPEWRITERS

REMINGTON $18.75. One machine only in new localities to secure desirable agent. Special agents prices supplied on all makes of typewriters. 3 ribbons $1.00. Standard Typewriter Exchange, 23 Park Row, New York.

Inquiry No. 9012.—Wanted to buy papier mache boxes in the shape of water melons, colored to resemble melons, etc.

MISCELLANEOUS

HAIR GROWS when our Vacuum Cap is used a few minutes daily. Sent on 60 days free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., 566 Barclay Block, Denver, Colo.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

WANTED.—Apparatus and films for moving picture show, also phonographic attachment for moving pictures and illustrated songs. Address Frank H. Goulette, P. O. Box 226, Manila, P. I.

LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Hoe Loomer process.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9018.—Wanted the address of parties manufacturing gold plated pens for use in cheap fountain pens.

Inquiry No. 9022.—Wanted to buy a light, small motor not exceeding three pounds in weight, including everything in going order.

Inquiry No. 9024.—Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

Inquiry No. 9026.—Wanted, address of parties who make "Invar" or other metals having a low coefficient of expansion.

Inquiry No. 9028.—Wanted to buy a washing machine that is run by a coil spring motor.

Inquiry No. 9029.—Wanted, addresses and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. 9030.—Wanted, the address of firms manufacturing a wood fiber bottle and case made from same material.

Inquiry No. 9033.—Wanted, the address of parties who supply carriage and wagon makers with white gum wood blocks for making hubs for vehicle wheels.

Inquiry No. 9034.—For manufacturers of machinery that could reduce stumps to kindling wood.

Inquiry No. 9035.—Wanted, manufacturers to make a metallic case somewhat similar to the "Thermos" bottle.

Inquiry No. 9036.—Wanted the address of the manufacturers of "Cycle Ball Bearing Suspenders."

Inquiry No. 9037.—Wanted, the address of the party who manufactures "Bakelite."

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

Inquiry No. 9039.—Wanted, machinery for the manufacture of salted peanuts.

Inquiry No. 9040.—Wanted, machinery necessary in the manufacture of tooth picks.

Inquiry No. 9041.—Wanted parties to manufacture a small wooden arrow for use in connection with a toy.

(Concluded from page 340.)

exceptions, from 1779 or 1785 to 1873, or a total of 88 to 94 years. While it might be possible that by coincidence the individuality of this continuous tenantry would continually vary, yet it is hardly possible that it was other than a case of a family castle handed down to posterity.

A fact which is incidentally brought out by these observations on the return of birds to a given locality, is the apparently passionate fondness for a given nesting site, regardless of changing conditions in connection with it. In illustration of this the author just quoted cites the case of a stone-curlew, *Œdicnemus crepitans*, a bird frequenting open places almost exclusively. For many years a pair of these birds had a nest at a certain spot near Elwedon, Suffolk, England, and during this period the environment underwent a complete change from a barren rabbit warren to a flourishing plantation, in the center of which the nest continued to be occupied. An even more remarkable example of fondness for a certain spot, regardless of change of conditions, was brought to the attention of the present writer several years ago. A portion of Long Island City, within the greater city of New York, was being built up on filled in marsh. During the fall and winter a plot of ground was filled in and a house built thereon. The following spring a Florida gallinule, *Gallinula galeata*, was repeatedly observed wandering disconsolately back and forth across the dooryard, seeking the site of last year's nest, though all about were patches of virgin marsh.

It seems quite possible that this fondness for a breeding home, once established, may be an important factor in the causes of migration.

Here then are some of the facts that command attention in the results of the data that has been accumulated regarding migration, the impulse to migrate for which we have no adequate and demonstrable explanation; the stability to steer a course with such remarkable accuracy over areas where landmarks are wanting, and in the night and storm when they are obliterated, demonstrating a most highly developed sense of direction which is but imperfectly present in the wildest races of mankind, and usually almost or entirely wanting in civilized man; the adoption of certain well-defined migration routes both in the Western and Eastern hemispheres which may be varied from spring to fall, or become changed by untoward conditions; the existence of this migratory instinct in varying intensity, which coupled with conditions of food supply and breeding sites induces in some species immensely extended journeys, from which there is every gradation to the species which are apparently immune to the promptings of this instinct. In connection with this last fact it should be borne in mind that the fact of a species being found in a given locality throughout the year does not necessarily imply that the individuals of that species are not migratory. The individuals found in a locality in winter may have summered further north, and coming to that locality in fall, overlapped the departing summer birds, so that at no time individuals of the species were wanting, though not at all times the same individuals.

80-DAY CRUISE TO THE ORIENT

By Twin-Screw S.S.
CINCINNATI (17,000 tons)
FROM NEW YORK, JANUARY 29th, 1910
COST $325.00 upward, Including Landing and Embarking Expenses

This cruise affords a splendid opportunity to visit the Orient under the best conditions that can possibly be offered by a company thoroughly experienced in the cruising field, having conducted pleasure cruises for the past twenty years.

TESTING BITUMENS.

(Concluded from page 336)

penetrated into the specimen. As it is desired to ascertain this with considerable accuracy, it is necessary to magnify the displacement of the rack. This is the office of the pinion and indicator. The dimensions of these are so arranged that a fall of 0.1 millimeter (=0.0039 inch) will correspond to one division on the dial.

Penetration at most temperatures is permitted for just five seconds. At the beginning the reading of the dial is noted, and also at the close. The difference will show the amount of penetration in terms of tenths of a millimeter. But if the test is made at the freezing point of water or at a lower temperature, the penetration is allowed to continue for a full minute. The weight carried by the needle is not always the same. For temperatures that do not rise above 32 deg. F., the weight is 200 grammes. At 77 deg. F. it is 100 grammes. For a temperature of 100 deg. F. or higher, the weight is reduced to 50 grammes. As the apparatus depending upon the needle weighs just 50 grammes apart from the weight *W*, the requisite variations in load are readily made.

The question arises here, however, as to whether there is any point of view from which the amounts of penetration at the various temperatures may be regarded as comparable. Thus Mr. Dow gives the penetrations of three different asphaltic cements, A, B, and C, as follows:

PENETRATION NUMBERS

Temperature.	A	B	C
32 deg. F.	10	13	25
77 deg. F.	55	47	45
100 deg. F.	150	110	75
115 deg. F.	350	220	120

The amount of penetration of A at 32 deg. F. is 10, at 77 deg. F. it is 55. But are the cases comparable? Can we say with any justice that the viscosity in the one case is 5½ times that in the other? The penetration of 55 was accomplished with half the load and in one-twelfth the time. Offhand it would seem that the number 55 should be 24 times as great.

There are, however, two other influence at work—one tending to make the number 10 too large, the other tending to reduce it. Falling bodies—and such a body the penetrating needle is—do not have a uniform velocity, but become accelerated. On the other hand, as pointed out by Mr. S. Whinery, the depth of penetration is not a measure of the work done, the needle being in fact of a conical form. The farther the penetration, the greater the amount of material displaced, and the greater the frictional resistance (due to adhesion) per unit of penetration. However, it is conceivable that the form and material of these counteracting factors might be so adjusted as to nullify each other.

With the disturbances arising from acceleration and from variation in resistance eliminated, there still remains the apparently faulty method of varying the weights and the time. It would seem better to maintain these factors precisely the same, or else correct the numbers so as to have them comparable, whatever the temperature. However, the Dow machine has, apparently, proved itself of great value in actual practice. An improved machine has recently been put on the market, in which the framework arrangement supplying weight for the needle is entirely discarded, being replaced by a tube containing the weight and holding the needle. This tube slides in a guide-arm supported by a substantial upright. The extra weight, as may be seen in the engraving, is placed low on the tube, and so will tend to deflect it but little, if at all. The table carrying the specimen is supported by a screw arrangement. This enables the specimen to be brought into contact with the needle at zero position. The mirror, seen at the bottom of the apparatus, enables the operator to determine when contact between needle and specimen has been secured. The counterbalancing arrangement used in the Dow apparatus is replaced by the pressure of a spring. The remaining features are essentially the same. The rejection of the framework device weighting the needle and the string counterbalance would seem to be steps in advance, especially if the replacements will yield as good results.

A practical word may be added as to the results shown in the table of penetrations. The cement A is regarded as showing as great a variation as is safe for pavement use. A greater variability in viscosity at the different temperatures would be difficult if not impossible in practical application. If soft enough for 32 deg. it would be too soft at high temperatures. C shows a steadiness which would be valuable if it were not for an accompanying bad quality. Its ductility (at 77 deg. F.) is but 20, while A is 300. B shows less variability in viscosity than A and more than C. Its ductility (at 77 deg. F.) is 75.

The susceptibility to change in hardness resulting from application of heat or to ageing may be ascertained by utilizing the penetrometer.

It will be seen from a consideration of the facts which have been recounted that the tests for ductility and viscosity are of great practical utility.

WANTED.—One third-class ship draftsman at $4.00 per diem. A competitive examination will be held December 15, 1909, to fill the above position. For further information address U. S. Superintending Naval Constructor, New York Ship Building Co., Camden, N. J.

The Middle West Number of the SCIENTIFIC AMERICAN

On December 11th, 1909, the Scientific American will issue a number devoted entirely to the wonderful Middle West region of the United States, a number which will set forth broadly and lucidly not only the agricultural interests of that region, but also those larger engineering undertakings which are destined to transform the Middle West, in part at least, into a manufacturing territory.

With that object in view the Middle West Number will publish articles on the following subjects:

I. The Chicago and Gulf Waterway.—An illustrated description of Chicago's drainage canal, an engineering work which stands without a parallel in the world.

II. Chicago as a Railroad Center.—Chicago is the greatest railroad center in the world.

III. The Wonderful Grain Trade of Chicago.—Chicago is an enormous wheat bin, into which much of the grain raised in the middle West is poured.

IV. Shipping on the Great Lakes.—Most of the iron ore that is now smelted in Pennsylvania is mined in the middle West. To transport it to the blast furnaces of the East at a cost which will enable American steel makers to compete with foreign steel makers, it has been necessary to devise a new kind of lake transportation. Ships of 10,000 and 12,000 tons burden have been constructed which convey ore at small cost through the Great Lakes, and which are without a counterpart anywhere in the world.

V. The Handling and Shipment of Iron Ore.—The above-mentioned fact that iron ore is mined in the middle West and smelted in the East has necessitated not only the construction of special freight-carrying steamers, but also the designing of special machinery for loading and unloading the ore from the steamers.

VI. Freighting on the Mississippi.—Freighting on the Mississippi is a more important industry than most of us may realize.

VII. The Steel Industry.—One of the greatest steel plants in the world is that which has been built at Gary.

VIII. The Freight Subway System of Chicago.—Chicago can boast of a rational system of handling freight by means of subways.

IX. The Water Supply of Chicago.—Chicago's source of water is Lake Michigan. The city is supplied with water by means of a tunnel which extends two miles out into the lake.

X. Reclaiming Arid Lands.—The United States Government has under way many irrigation projects for the purpose of reclaiming lands which are arid but which will blossom if properly watered.

XI. Harvesting the Grain of the Middle West.—Farms that cover not acres but square miles, crops that aggregate not simply bushels but car-loads, have rendered it necessary to plant and harvest on an unprecedented scale in the middle West. The ingenious agricultural machinery which has been designed to cope with these peculiar conditions is described and illustrated.

The Middle West Number will be more than twice the size of the regular SCIENTIFIC AMERICAN. It will be lavishly illustrated. It will be contained in a colored cover which strikingly depicts Chicago's grain elevators at work. Order from your newsdealer or from

A Clean Shave

All new blades need stropping before using. Not one in ten comes sharp enough for a clean shave.

Why scrape your face with dull blades, or continue to throw away money for new ones, when the Gaylor Automatic Stropper will resharpen all your dull blades in a few moments, giving them a hairsplitting edge better than new. The motion is automatic; no practice required; a child can use it. It is the only stropper in the world that successfully sharpens double-edge blades.

Price $1.00

In case with barbers' genuine Horse Hide Strop, $2.00

Order through your dealer. Or will send postpaid on receipt of price. Be sure to state for what make of Blade. Money willingly refunded if not entirely satisfactory. Write for descriptive circular. Agents wanted.

USES A STUB OR ANY STEEL PEN

Sanford Fountain Pen $1.00

Everyone who uses a pen ought to know about the Sanford Fountain Pen, which uses an steel pen. Patented Feb. 28, 1905. A remarkable improvement in fountain pens. Office Men—Book-keepers—Shorthand Writers use and endorse it enthusiastically.

"Don't Drop a Drop of Ink"

It is made of best hard rubber in 3 styles, chased plain barrel and shorthand size. Gives a smooth, steady flow of ink. Positively will not leak or drop ink. Pens can be changed easily.

Pocket Clip 10c.

10 DAYS FREE TRIAL

The Sanford Fountain Pen is of the highest quality at a very low price. We know that it is equal, if not superior to any high priced pen made. We are willing to prove this to you. Mail us one of your favorite steel pens, and we will send you a complete Sanford Fountain Pen postpaid. After 10 days' trial, if you are satisfied, send us the regular price $1.00. If not, return the pen to us. This shows how much confidence we have in it. Isn't this a fair offer? You be the judge.

The Sanford Manifolding Pencil is a great convenience for users of indelible pencils. All parts hard rubber—dust proof—no stained fingers. Price 50c. postpaid, including set of indelible leads. AGENTS WANTED EVERYWHERE. Send for booklet.

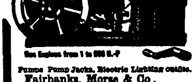
Perfect One Horse-Power Engine

This great pumping or power engine is within the reach of every countryman's pocket-book. At last farmers can obtain a one horse-power high grade **Fairbanks-Morse Engine** at a very low price. "Jack Junior" is a four cycle gasoline or kerosene engine with a hopper water cooling jacket, which does away with the large quantity of water for cooling required by other engines. It is mounted on wood base, complete with battery all ready to run. Weight, over 300 pounds.



See Engines from 1 to 500 H.-P

Don't confuse this sturdy worker with toy air cooled engines made merely to sell. **Jack Junior** is as durable and reliable as the highest priced engines you can buy and should give perfect service for years at less than 1 cent per hour for fuel. Will run any machine that does not require over one horse-power. Will pump more water than any ordinary windmill. Cut out advertisement and send for big illustrated Engine Catalog No. BO 1005. Pumping Engines, Pumps, Pump Jacks, Electric Lighting outfits, Saw Frames, Grinders, Shellers and Supplies.

LOCAL MAGNETIC DISTURBANCES AND THE GENESIS OF PETROLEUM.

In a bulletin recently published by the Geological Survey, Mr George F Beiker ingeniously inquires whether there is not a hitherto unsuspected relation between magnetic disturbances as manifested by the compass needle and petroleum deposits. Any such attempt must necessarily be based on some definite theory of petroleum's origin. Accordingly Mr Beiker summarizes the condition of knowledge with reference to the origin of petroleum and other bituminous substances. The result is thoroughly unsatisfactory Some oils are undoubtedly organic and some are beyond question inorganic. The evidence shows that neither variety can properly be regarded as unimportant. Mr Beiker's review, however, does not elucidate the source of the principal deposits, the great petroleum pools. They may have been derived from carbonaceous matter of vegetable or animal origin, and they may have been derived from carbides of iron or other metals It is also barely possible that the hydrocarbons exist as such in the mass of the earth

In thinking over this situation it occurred to him to inquire whether any relation could be detected between the behavior of the compass needle and the distribution of hydrocarbons. Not very much could be expected from a comparison of these phenomena, for magnetite exerts an attraction on the needle whether this ore occurs in solid masses or is disseminated in massive rocks, and again, many if not all volcanic rocks possess polarity so that repulsions are involved as well as attractions. Even if the iron carbide theory of genesis were known to be correct, and exclusively correct, no one would think of maintaining that all bodies of magnetite have a connection, however remote, with the occurrence of petroleum Hence any indications of iron carbides and associated petroleum which the compass might be supposed to afford would be obscured by the local attraction of independent masses of magnetite. Earth currents are also to some extent local and thus produce irregularities in declination.

Nevertheless, irregularities of the curves of equal declination on Bauer's map of the magnetic declination in the United States, are strongly marked in the principal oil regions When this map is compared with one prepared by Mr David T Day showing in detail the known hydrocarbon deposits of the United States the coincidences recognized become more striking and other agreements become evident

The most marked agreement is found throughout the great Appalachian oil field which is the area of greatest variation in declination In California, also, strong deflections of the isogonal lines accompany the chain of hydrocarbon deposits. In the interior of the country the coincidences are less marked, but they are very noticeable

There are other systematic irregularities, wrinkles in the isogonic topography which can not be connected with oil One such wrinkle runs down the Atlantic coast and contains the New Jersey native iron as well as known deposits of magnetite. Another lies near latitude 37 deg. and is doubtless due to the great northern iron belt.

No detailed chart of the magnetic declination in the petroleum fields of the Caucasus has yet been prepared. Mr Bauer states that great magnetic disturbances exist in that region, so that relations [illegible] similar to those in this country are probable.

On the whole, coincidences between the occurrence of petroleum and local disturbances of the compass needle are too numerous to be attributable to mere accident or chance. There must therefore be a direct or an indirect historical connection between the two phenomena in the regions of coincidence.

No one doubts the vast industrial importance as well as the deep geological interest of the petroleum question. As time elapses it will grow more and more important, for the pinch of dwindling coal resources will probably affect children of those already born. In the interest both of the development and the conservation of our natural resources all the means at the command of science should be brought to bear on this mysterious subject. A geologist and a chemist each of the highest order should be coupled in the long and difficult investigations needed to elucidate the genesis of petroleum. The initial expense would be considerable, but the ultimate economy would be enormous.

THE FIFTH VANDERBILT CUP RACE AND THE GOOD ROADS TOUR FROM NEW YORK TO ATLANTA.

It is seldom that the public has an opportunity to witness notable speed and reliability contests contemporaneously, but such was the case this year when the Vanderbilt cup race was run on Long Island on October 30th, while the reliability tour promoted by the New York Herald and the Atlanta Journal was also being conducted

Although the race has lost much of its former glamor through the substitution of high-powered stock chassis for the huge racers that used to compete, it nevertheless gives a good idea of the speed and endurance qualities of the machines that are being regularly produced for the market.

The fifth annual race was run over a 12.64-mile course, which included the cement motor parkway upon Long Island, and consisted of 22 laps (278.08 miles) There were 15 competitors, while the four stock cars that took part in the Wheatley Hills Trophy race and the six in the race for the Massapequa Trophy, both of which were run simultaneously, made a total of 25 machines that were traveling around the course at the start. The two secondary races were 189.6 and 126.1 miles in length respectively, and were for cars of smaller horse-power and lighter build

The Vanderbilt race was won by the 60-horse-power 6-cylinder Alco car driven by H F Grant. The time was 4 hours, 25 minutes, and 42 seconds. The average speed maintained was 62.77 miles an hour, as against 64.38 made by Robertson last year on a better course with a 120-horse-power Locomobile During the last four rounds an average of over 70 miles an hour was maintained, the last one being covered in 10 33 at the rate of 71.9 miles an hour This machine—an improved American model of a well-known French car—has always done well in all contests in which it has been entered, and it was not at all surprising that it should win America's premier racing event.

The only other car to finish was Parker's Fiat, which averaged 61.55 miles an hour Only two other cars—an old Mercedes and the two-cycle Atlas—were running at the end. This is said to have been due to the use of the motor parkway as more than half the course, which was only half the length of those used in previous years. The cement surface of this road has slight undulations that make it a very severe test of both tires and mechanism. Two cars broke their steering knuckles, four had cracked cylinders, and three sustained a broken crankshaft, a broken rear axle, and a damaged radiator, respectively

The 189.6-mile race was a walkover for Harroun on a Marmon, as the three other cars in the race lost many minutes making repairs, and one of them withdrew when the race was half done. The average speed of the winner was 59.76 miles an hour

The 126.4-mile race was won by a Chalmers-Detroit 30-horse-power car in 2 hours, 9 minutes, 53 2/5 seconds at an average speed of 58.4 miles an hour Two Maxwell machines were second and third with an average of 51.1 and 50.4, respectively, while a 30-horse-power Hudson secured fourth place with a 50-mile-per-hour average.

The reliability tour which was promoted for the purpose of spreading the good roads doctrine by giving the farmers of the South an ocular demonstration of the value and usefulness of the automobile, especially where good roads obtain, was carried out with marked success. Forty-seven cars left New York on the morning of October 25th and covered the 1,150 miles of varying kinds of roadway passing through nine States and leading to Atlanta in ten days without serious trouble. Twenty-[illegible] of these machines made the journey on schedule time with a perfect score. [illegible] were divided into six classes ranging in price from [illegible] down to $850. The Maxwell [illegible] was the sole prize-winning representative of the [illegible]. This reliability [illegible] newspapers, [illegible]

[illegible]

[illegible]

It is a somewhat singular fact that [illegible] household beverages, coffee, tea, and cocoa, [illegible] an alkaloid, a poison. In small doses these alkaloids have a certain stimulating effect upon the system, and it is presumably on this account that the beverages which contain them have acquired such popularity. At the same time there seems to be no basis for the belief that these beverages act as aids to the digestion, and the fact remains that the alkaloids of coffee, tea, and cocoa are toxic substances. Their ingestion in excess may become harmful even to strong and healthy persons. For this reason endeavors have been made to find suitable substitutes, which should possess the advantages and pleasing properties of our common household beverages, but free from the poisonous constituents which these latter contain.

We must look to special processes of treatment of ordinary coffee for our supply of a non-toxic product free from alkaloids. One such process, the product of which is upon the market, consists first in a preliminary treatment of the coffee beans, whereby their cell tissue is loosened. They are next subjected to the action of acid or alkali, and the caffein can then be extracted with a volatile solvent, such as benzene, ether, chloroform, petroleum ether, etc. The residue of solvent left in the material after the extraction is expelled by treatment with high-pressure steam or in vacuo.

A new process, invented by Prof. Klippenberger, who has abandoned his patent claims and made the method public property, consists in treating the coffee with oil, and subsequently with acetone or glycerine.

The inventor has found that caffein is insoluble in oil at ordinary room temperature, but is readily soluble in hot oil Furthermore, caffein tannate, which is present in coffee side by side with free caffein, while practically insoluble in ether, benzene, and chloroform, is readily soluble in glycerine and acetone.

The new process accordingly consists in treating the coffee with fatty oils (glycerides) at temperatures and pressures at which the glycerides are not decomposed. After this step the coffee is freed from adhering liquid in any suitable manner, e. g., by centrifugal action The oil may be freed from caffein either by simply allowing it to cool, when the alkaloid is precipitated, or by extracting with a suitable solvent. After this treatment the coffee still contains a small proportion of caffein, namely, that which is present "bound" in the form of tannate. This can be eliminated by treatment with glycerine or acetone or both. If preferred this step can be carried out before the treatment with hot oil. The temperature in this latter should not exceed 160 deg. C., for decomposition of the glycerides must at all events be avoided.

In place of the glycerides (oils) it has been found that quite a large number of other substances can be used. One condition which they must satisfy is that they should be liquid at say 100 to 150 deg. C. Among substances may be mentioned the aliphatic hydrocarbons, and those of the aromatic series; also derivatives of the latter, especially their alkyl and chlorine substitution products, further the higher alcohols, ethers, and esters, such as amyl alcohol, amyl ether, and ethyl acetate. But none of these substances is quite as well adapted as the glycerides for the extraction of the caffein, as they leave a residue behind the complete elimination of which is attended with some difficulty

The treatment with oil does not only extract the caffein, but also certain resinous substances. As the result of this the taste of the coffee is improved. In the case of tea the conditions are less favorable. Here the process causes the loss of certain of the constituents which impart its characteristic aroma to the tea. The results of the extraction of coffee with glycerine and acetone also are not entirely satisfactory. To an expert taster the product appears not quite unaltered. To the ordinary consumer, however, it is quite indistinguishable from the natural untreated ware.

The principal object of a recently designed clock is to show at a glance, says the Journal of the Royal Society of Arts, the time all over the world. In front of it a dial is mounted, which revolves with the watch once in 24 hours, having the hours 1 P. M. till 12 midnight, and 1 A. M. till 12 noon, painted on its periphery, the hours being divided into intervals of [illegible] minutes each. In the same plane as the dial is fixed [illegible]

[illegible]

[illegible]

[illegible] in the Subway and [illegible] the Hudson- [illegible] passengers being carried [illegible]

[illegible] engine has been designed by [illegible] and T. C. Aveling, intended [illegible] which prevent such engines [illegible] by the shaft of a vehicle, as in [illegible] engine.

[illegible] now made in the Panama Canal [illegible] September last is 27,172,658 cubic yards, [illegible] three hundred yards short of one-[illegible] the total excavation required. As the average [illegible] excavation is over 100,000 cubic yards, it may [illegible] be said that half the work was done by the end of the first week in October.

The hurricane in New Orleans on September 20th [illegible] an interruption in the operation of the pumps of the drainage system, owing to their being electrically operated and the overhead transmission line being blown down. Temporary wires were strung up [illegible] on telegraph poles, and pumping resumed in 48 hours, but it is now proposed to build a duplicate transmission line, and eventually to put the whole of it underground.

In connection with the landing of the Cunard steamers at Fishguard in Wales, the Great Western Railway of England has put on a new special train to London, which has been making remarkable time. On a recent run a train with a total weight of 300 tons was drawn by the new engine "King Edward" from Fishguard to London, 261 miles, at an average speed, including one stop of four minutes, of 61.2 miles per hour.

An improvement much needed elsewhere also is being tried by the Chicago Railways Company for the forced ventilation of street cars. A double ceiling is used with a number of openings like those of a hot-air heating system, the space between upper and lower ceiling acting as an exhaust duct. Fresh-air intakes are cut through the floor near the sides of the car, the screened air admitted passing through electric heaters under the seats before entering the interior of the car.

A remarkable piece of work was done by Messrs. David Rollo & Son of Liverpool in the fitting of a new high-pressure cylinder of improved design to the steamer "Star" of New Zealand The vessel being engaged in the meat trade, it was desired if possible that the change should be made in the time required to discharge her cargo at Liverpool; and although it involved the machining and fitting of all auxiliary parts, it was completed in five and one-half working days.

One of the unusual features of the work on the Ashokan reservoir in the Catskills is the use of special steam rollers for "puddling" the earth fills on either side of the concrete core-walls of the dikes. Over six million cubic yards of earth must be spread in six-inch layers, moistened and rolled, eventually forming a dam 200 feet high in places and four miles long, so the work of the rollers is considerable. They have corrugated front rolls and cross-cleats on the rear rolls, so as to thoroughly knead the moist earth, and each covers the work done by thirty men, a dozen teams, and a cableway, and is guaranteed against breakdown in continuous work for seven years.

In the House of Commons recently the question was raised as to whether the Home Office would consider the question of compelling tramway authorities to fix on their cars a device for making a continuous noise when the speed exceeds a certain limit, as is now done in the case of motor omnibuses. Mr Masterman replied that the question was under consideration, but the application of the device to tramcars presented special difficulties, owing to the varying limits of speeds [illegible] for tramways. Mr. Myer asked if Mr. Masterman was aware that some of the cars on the Thames Embankment traveled at a speed of over 20 miles per hour, but no answer was given.

[illegible] has been much favorable comment in the engineering press upon the completion, in six months less than the contract time and well within the estimated cost, of the widening of Blackfriars Bridge in London. [illegible] which is [illegible] years old, consists in its [illegible] of five iron arches ranging in span from [illegible] and the masonry piers founded on [illegible] filled with concrete, the original [illegible] having been removed and the [illegible] The work completed last [illegible]

ELECTRICITY.

It is reported that a series of wireless telegraph stations are to be installed in Siberia which will enable the War Department of Russia to keep in communication with the easternmost parts of the empire. These stations are to be large enough to operate over a radius of a thousand miles.

It has been suggested from time to time that the air in the subway could be rendered less obnoxious by supplying each car with apparatus for producing ozone, but the mere conversion of oxygen already in the subway into the form of ozone would not solve the difficulty. What is needed is a fresh supply of oxygen to take the place of that consumed by the passengers and converted into carbon dioxide. A recent editorial in the Electro-chemical and Metallurgical Industry calls attention to the system of Dr R. Von Foregger, who a few years ago proposed the use of fused sodium peroxide. Water added to this chemical would cause the production of sodium hydroxide and would liberate oxygen The sodium hydroxide would then absorb the carbon dioxide of the air and thus in addition to furnishing a fresh supply of oxygen it would purify the air as well.

Strange as it may seem to the uninitiated, the cost of operating an electric car depends to a large extent on the motorman. The economical motorman will permit his car to coast whenever possible and in this way will effect a considerable saving of power Each application of the brakes means a waste of power Recently an apparatus has been devised for keeping a record of the periods of coasting of different cars. The device is connected both with the electrical controller and with the air brakes and operates only when both the controlling apparatus and the brakes are in the 'off" position. The record is made on a paper ribbon driven by a clock. This record makes it possible to judge of the relative economy of different motormen operating on the same line and encourages them to let the cars coast whenever it is possible to do so without falling behind their schedule.

One of the main advantages of electrifying a railroad system lies in the fact that instead of having a large number of portable power plants represented by the locomotives, all the different power units are brought together in one central station and thus considerable economy is possible, if for no other reason because a separate reserve power is not required for each train. The same argument applies to the centralizing of central power stations. Instead of having different concerns manufacture their own electricity the power could all be generated in one large station Recently the New York Edison Company has offered to furnish power for the Broadway-Lexington Avenue subway The Edison Company points to the fact that it is well equipped to furnish the power required and has an adequate reserve to meet all demands.

Replying to the popular demand that the Illinois Central Railroad should electrify its terminal in Chicago, President Harahan points out the fact that electric traction is still in the experimental stage and that little as yet is known of the use of electricity for handling freight. The Illinois Central is obliged to interchange trains and cars with other roads and considerable inconvenience would be occasioned by the use of electric traction in its freight yards. He also suggests that the smoke nuisance could be eliminated by other means, and until a comprehensive plan has been developed for electrifying all the railroads that enter Chicago it would be impracticable for the Illinois Central to make a change in the power it uses. The railroad is making experiments with cars operated by gasoline engines and is testing the use of coke instead of soft coal. As a matter of fact, the railroads of Chicago contribute only a small portion of the smoke that clouds the city However, the City Council is considering an ordinance which will compel every railroad in Chicago to use electricity

The extensive use of trackless trolley cars in continental Europe has led British manufacturers to make experiments with a view to producing a type particularly adapted to the requirements of their own traction systems. Recently a car has been developed which possesses many very interesting features. Chief of these is the trolley head and its connection to the car. A three-wire system is used, the current being collected from two outer wires while a central wire takes the place of a ground. The head is supported in a horizontal position by means of a sort of parallel-ruler connection, there being two poles connecting it with the roof of the car. The head can be converted into a single-pole trolley head whenever it is desired to run the car on a track system, and in this case the [illegible] is taken care of by a pair of shoes which ride on the track. The overhead wires are so arranged that they can be adapted for a track system at a minimum [illegible] whenever the traffic makes such a change [illegible]. It is merely necessary to remove the outer wires and leave only the central trolley wire.

SCIENCE.

Jean Comandon announced before the Academy of Sciences on October 27th the development of a new method of photographing bacilli by the combined use of an ultra-microscope and a cinematograph.

After examining the documents presented for consideration by Lieutenant-Commander Peary, the National Geographical Society has reached the decision that he reached the North Pole, and has decided to award him a gold medal for his exploit.

A cablegram has been received at Harvard Observatory from Kiel stating that Winnecke's comet was observed by Pons of Laplate, Oct 31 d 5040 Gr M T, in R. A. 17 h 11 min 51 6 sec Dec. —27 deg 18 min 43 sec The comet is visible in a small telescope

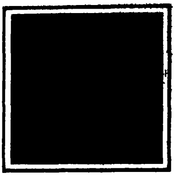
Prof. Metchnikoff, as our readers well know, advocates the drinking of much fermented milk to check the intestinal putrefaction of food and thus prolong life In furtherance of his end bonbons have been prepared consisting of a lactic acid product surrounded by a sweetened chocolate coating The sugar of the coating assists in lactic-acid fermentation.

An alloy which may have a considerable value for steel processes is now manufactured in the electric furnace in France. This is the mangano-silicide of aluminium formed of manganese silicon, and aluminium, containing generally from 1 to 2 per cent of iron and 0 25 per cent or less of carbon Sulphur and phosphorus are practically absent The new alloy has been found to answer very well as a de-oxidizing agent in steel making During the refining it is transformed to silicate of manganese and aluminium, giving a very fusible slag which is easily separated from the melted metal It is claimed that the steels which are obtained by the process are very homogeneous and are free from porosity The proportion of the new alloy is about as follows Manganese, 75 per cent, silicon, 37 per cent, and aluminium 18 per cent In the steel process, 100 parts of alloy combine with 71 parts of oxygen to give 171 parts of slag

The $1,000,000 given by John D Rockefeller will go a long way toward eradicating the 'hookworm" The worm was identified in 1903 by Dr Charles Wardell Stiles of the Rockefeller commission Soil pollution is responsible for the existence and spread of the worm It can be eliminated from the human body by a simple treatment of thymol and Epsom salts the patient in most cases being cured in several days. Pronounced anemia is the chief symptom of persons afflicted with the hookworm disease, accompanied by emaciation and great physical weakness Laziness, mental lassitude, and stupidity are other symptoms. Uncinariasis is the technical name for the disease Hookworm disease was probably known to the Egyptians near 3 000 years ago, but its cause was not understood until about the middle of the nineteenth century The hookworm is about half an inch long It lives in the small intestine.

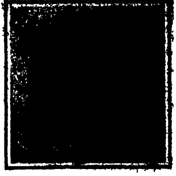
Once it was possible to buy radium at $2 a milligramme, now the market price is $90 a milligramme, equal to $2,500 000 an ounce. This was one of the striking statements in a very interesting speech delivered by Sir William Ramsay at the foundation stone laying ceremony of a new radium factory in Limehouse, an eastern suburb of London The British Radium Corporation, which is going to extract radium from pitchblende found in the Trewith mine, Cornwall, is believed to be the first company in the world to attempt the production of the precious mineral on a commercial basis It is one of the romances of science that the material in the old days was regarded by the Cornish miners as a nuisance, for it prevented them from obtaining copper from smelting. For a long time it was cast on the dumps or left underground. To-day the comparative value of crude pitchblende ore *is far in excess of the gold quartz of Johan*nesburg or the blue earth of the diamond mines.

The swamp potato (*Solanum Comersonii*) which grows wild in Uruguay has lately been cultivated in France, where it has produced a variety with violet tubers. The new variety is characterized by extraordinary productiveness, resistance to disease and frost and the production of large aerial tubers in the axils of the leaf stalks German potato growers, however, find the new variety so similar to the long-known variety "Paulsen's Blue Giant" that they are inclined to think that the latter has, innocently or designedly been exploited in France as a novelty The same opinion is held by a prominent English potato grower The two sorts have also been cultivated side by side at the experiment station of a Swedish society for the improvement of moors, where they appeared to be identical in foliage, flowers, and tubers The swamp potato, however, proved less productive than the old Blue Giant, and its most strongly emphasized peculiarities, antipathy to lime and preference for marshy soil, could not be detected. Similar results were obtained on an experimental plantation in Silesia.



ARCHAEOLOGICAL RELICS FROM THE SEA.

BY FERDINAND WORTHINGTON



In 1907 a Greek sponge-fishing craft discovered three miles off the coast of Madhia between Sousse and Sfax at a depth of about 150 feet the wreck of a vessel some 100 feet long and 20 feet beam The cargo of the sunken vessel consisted of sixty columns of white marble arranged in six rows the columns being topped with Corinthian or Ionic capitals and otherwise painstakingly and artistically carved Furthermore there were several statues.

M A Merlin Director of Antiquities of Tunis has advanced the theory that the vessel was an ancient galley which had left Greece bound probably for Italy Contrary winds had driven it on the coast of Tunis where it foundered at a time which may be approximately placed at about the beginning of the Christian era

The relics which have been brought to the surface from this ancient wrecked ship are undoubtedly of Greek origin Several bronze statues have been recovered One of them a figure of Eros is thought to be a replica of the Eros of Praxiteles There is also a Hermes of Dionysus fragments of candelabra and of beds also a statuette about 14 inches high which might have served as a lamp for the head is hollowed out to form an oil well

The marble relics are more numerous than those of bronze They comprise capitals of various decorative designs drinking cups embellished with Bacchic bas-reliefs which remind one of the celebrated Borghese vase of the Louvre statuettes busts and the like. One column which was brought ashore measures 13½ feet in height, and nearly 2 feet in diameter at the base

It may be stated that this artistic treasure trove of the sea was recovered at the expense of the Tunisian and French governments the Académie des Inscriptions et Belles Lettres and several wealthy gentlemen The French navy assisted in bringing the material to the surface. The divers employed were Greeks who had forsaken their calling of sponge fishing to devote themselves to the more artistic vocation of fishing for statues All the objects which have been recovered will eventually find a placé in the Bardo Museum at Tunis.

A Pure Air Law for Workmen.

BY G. M. RIPLEY

It costs money to purify anything Whether it be the Panama Zone that must be made habitable or a political situation which requires a housecleaning all of these worthy enterprises require considerable expenditure and there will always be found some who protest Even our worthy pure food law came in for its share of complaint and now we learn that the New York labor law requiring a supply of fresh air for the employees of workshops and factories is being subjected to some criticism

The law reads as follows

The owner agent or lessee of a factory shall provide in each work room thereof proper and sufficient means of ventilation and shall maintain proper and sufficient ventilation if excessive heat be created or if steam gases vapors dust or other impurities that may be injurious to health be generated in the course of the manufacturing process carried on therein the rooms must be ventilated in such a manner as to render them harmless so far as is practicable

Mr William W Walling chief factory inspector for the State of New York interprets the law as follows

As defined by Dr John S Billings perfect ventilation means that any and every person in a room takes into his lungs at each respiration air of the same composition as that surrounding the building no part of which has recently been in his own lungs or those of his neighbors or which consists of the products of combustion generated in the building while at the same time he feels no currents or drafts of air and is perfectly comfortable as regards temperature being neither too hot nor too cold. How much air is required to meet these conditions? Not less than 2,000 cubic feet per hour for each person, with the same amount per hour for each cubic foot of gas consumed whether for light, heat, or power

Some landlords in New York city have put forth the claim that the amount of fresh air specified by the Department of Labor was an arbitrary quantity" Several authorities on the subject of ventilation who have been consulted in the matter and who are also entirely disinterested agree that 2 000 cubic feet per hour per person is common practice and is based upon definite laws or rules which have been followed for many years in the design of ventilating systems

The Architects and Builders *Pocketbook*" written by Mr Frank E Kidder C E Ph.D states (and this book is an authority and therefore a record of current practice) that 1 800 cubic feet per hour per child should be the standard for school buildings this amount being required by law both in Massachusetts and New York. It further states that in buildings more closely packed and occupied for a longer period the air supply should be from 2 000 to 2 500 cubic feet per hour per person In giving an example of a school room of certain dimensions he shows that the standard amount of air would result in the air in the room being changed about eight times per hour—which certainly does not appear to be an excessive amount

Since the above applies only to buildings where people sit quietly or for buildings where only children congregate it is difficult to see how the representatives of the New York Department of Labor can justly be accused of any arbitrary action in interpreting the meaning of proper and sufficient ventilation

Mr Percival Robert Moses consulting heating and ventilating engineer of New York city states that he has found the rate of 2 000 cubic feet per hour per person a satisfactory and conservative working basis

In a loft 25 feet wide and 100 feet long containing

[illegible]

Fishing for archæological relics.

80 workmen, and lighted with electricity, the amount of air required would be 80 × 2 000 = 160,000 cubic feet per hour This amount of air per hour would move at the rate of about ⅛ of a mile per hour, and would be sufficient to change the air in the loft six times per hour, assuming a 10-foot ceiling Since the Massachusetts and New York State laws for school rooms require eight changes per hour, and since some authorities recommend even 50 per cent in excess of this, it appears that the action of the factory inspector hardly comes within the definition of the word "arbitrary" which in the Standard Dictionary means "done capriciously" or "without adequate determining principle," or "non rational," not done according to reason or judgment, depending on the will alone, tyrannical, despotic, not fixed by rule

The operating cost for a ventilating system is made up of two items (1) Power for turning fans, (2) additional heat for incoming air In a loft building where the tenant will pay for the power, the expense will automatically be divided and the landlord will pay for the extra heat required, since heat is included in the rent. It will also be noticed that again the adoption of electric lighting will cut the bills for operating expense to a remarkable degree. This cut in expense will affect the tenant, since a much smaller ventilating motor will be required, and it will also affect the landlord because less air will have to be drawn in, and hence the cost for heating would be diminished

In large systems the services of an expert heating and ventilating engineer would probably prove valuable, and it is possible so to design the equipment that a judicious "recirculation" of the air from halls and basements will effect an economy in the fuel bill This air is seldom impure and requires much less heat than if cold air were brought in from outside It is also possible in buildings where high-pressure steam is available, or where boilers which have been run at low pressure can be run at a higher pressure, to adopt the following policy: Provide steam engines to operate the fans and turn the exhaust steam into the heating coils—thus getting a double use out of the steam and cutting down the electric bill. This idea could be carried still further in many instances, and economies could be made (especially in the winter) by abandoning electric pumping, again lowering the electric bill. This is the stock argument of the advocates of isolated plants, who contend that great economies result in buildings of a million cubic feet or more if engines are installed and electricity is made on the premises. It is a fact that steam at high pressure only contains about 6 per cent more heat than steam at low pressure. Thus the argument that electricity can be made and a building heated with exhaust steam is advanced. The layman does not appreciate one very peculiar fact about steam: that at five pounds pressure it is only about 6 per cent cheaper to make than at 100 pounds pressure, showing that the cost does not increase in proportion to the pressure.

[illegible]

of this character has recently been completed in New York city, in which the landlord at the time of construction had the ventilating system installed at his expense, after the design of a prominent consulting engineer Thus the cost of operating a system and the responsibility of maintaining it in good condition does not rest upon the tenant

It is natural during this transition period and before the betterment of the standard of building construction has become general, that some differences are bound to arise between the Factory Inspection Bureau and the landlords and tenants. It is to be hoped that this condition is but temporary

In the report of the United States Bureau of Labor at Washington, D C., it is shown that deaths among factory workers due to consumption, were divided as follows

Employees exposed to metallic dust	36 9 per cent
Employees exposed to mineral dust	28 6 per cent
Employees exposed to vegetable fiber dust	24 8 per cent
Those exposed to animal and fiber dust	32 1 per cent

The occupation showing the highest consumption mortality was grinders, among whom 49 2 per cent of all deaths were from that disease

An ingenious conclusion was reached by Mr Frederick L. Hoffman, of the Prudential Life Insurance Company, based on this report. It is his opinion that by intelligent methods of ventilation and dust removal the consumption death rate among the wage earners would result in an annual saving of 22,238 lives. This would add, quoting the Engineering News, 15 4 years of life for every death from consumption avoided by rational conditions of industrial life Such a gain would represent a total of 342,465 years of additional lifetime, and by just so much the industrial efficiency of the American nation would be increased Placing the economic value of a year's lifetime at only $200 the total average gain to the nation would be $3 080 for every avoidable death of a wage earner from consumption, representing the enormous total of $68 493 000 as the annual financial value clearly within the range of practical attainment. Therefore nothing within reason should be left undone as a national, State, and individual or social duty to prevent that needless but now enormous loss of human life from consumption due to the unfavorable conditions in American industry

None will deny that the efficiency of workmen varies with their good health and comfort Slight physical ills are prevented by better surroundings, and the loss to the employee due to absences, or brain made stupid by breathing foul air, are immediate losses to the employer through lowered efficiency, and later involve a loss of trained employees and the necessary breaking in of green help

The Technical Utilization of Platinum.

Platinum is one of the most important substances used in modern industry Its resistance to attack by strong sulphuric acid makes it a suitable material for the vessels employed in concentrating the dilute acid of the lead chambers, and until recently, states Umschau platinum vessels were always used for this purpose Its permanence in the air makes it suitable for contacts in electric bells induction coils and the like its resistance to the action of chemical reagents causes platinum to be employed in the construction of crucibles, evaporating dishes scale pans, etc, as well as electrodes for experimental and technical electrolysis. Platinum is little affected by heating to a very high temperature and it is consequently used in the construction of electric resistance furnaces, in which temperatures exceeding 1 800 deg F are attained and in Le Chatelier's pyrometer for the measurement of high temperatures. Another property of platinum which is of great practical importance is the approximate equality of its coefficient of expansion by heat to that of glass or porcelain A platinum wire fused into a glass vessel will not produce cracks or leakage by unequal contraction in cooling or unequal expansion in subsequent heatings. This property is utilized by the makers of incandescent electric lamps, the carbon filaments of which are connected with the external circuit by short platinum wires, fused through the glass bulbs For a similar reason the attachments of artificial teeth are made of platinum wire which is baked with the porcelain mass in the kiln Finally the catalytic properties of platinum are utilized in various chemical industries especially the production of sulphuric acid by the contact process, and in the construction of self lighting gas burners etc

The Rising of the Aral Sea.

The rise which has been noticed in the Aral Sea is a difficult one to explain It will be remembered that this body of water is one of the greatest lakes in the world, and in some places it has a depth of 220 feet It receives the water of two large rivers the Amu Daria and the Syr Daria which bring to it about 2 000 cubic yards per second During the last century it appears that the level of the lake has varied considerably Starting from the middle of the century, we find that the level was lowered during 30 or 35 years, and this condition prevailed until after 1880, bringing about changes in the contour of the lake and the islands became larger However we find that in 1899 when Berg explored the lake, it was now rising and had reached a much higher level, so that it overflowed some of the islands and these had to be abandoned On shore the railroad tracks had to be moved The rise in the lake lasted until 1908 and we find that from 1880 to 1901 the level of the lake rose about 6 6 feet Besides the Aral Sea we find that other lakes of the same region have also risen, so that the region of central Asia is far from undergoing a gradual drying up as was supposed Given the mean depth of the lake as 52 feet, the rise of 6 6 feet gives the addition of a mass of water representing one-eighth of the lake's contents. At the Barnoul observatory the rainfall is found to have kept at about the same point since 1877 so that we are at loss to explain the rise of the lakes in this region In ancient epochs we find similar phenomena in different lakes as determined by geologists but like the present one they appear to be unexplained

OUR AERONAUTICAL ORGANIZATION.

BY C. H. CLAUDY

Except for sporadic experiments, as at Fort Myer last year for all the majority know to the contrary, the United States has done nothing in aeronautics. But the impression is erroneous. We have done all that we could do with the money there was available—more indeed, than anyone thought we could.

Just what is our status, aerially, to-day?

To begin at the beginning, the aeronautical work of the government is all in the hands of the Signal Corps, an arm of the service charged with obtaining and conveying information, and opening lines of transmission of intelligence Within the Signal Corps, of which Brig-Gen James Allen is chief, is the Aeronautical Division This includes a number of officers, of whom Lieut Frank P Lahm is chief, under Gen Allen, and enlisted men in squads of varying proportions, depending on the work to be done. Major G O Squiers is the theoretical expert. The strange proportion of men to officers of about two enlisted men to each officer which obtains is explained by the fact that the enlisted men do nothing but erect the balloons or act as laborers for the towing or holding of aeroplanes. It is the officers alone who do the flying and to whom is intrusted the actual aerial work. An exception to this was found last year when on the death of Lieut. Thomas Selfridge in the Wright accident and before Lieut. Lahm could get to St. Joseph, Mo, where the dirigible was located, Sergt. Ward went up in the dirigible with Lieut. Foulois and while without experience succeeded in operating the steering end with credit

By name the officers in the aeronautical corps are Lieut. Frank P Lahm Major George O Squiers Lieut Benjamin D Foulois Lieuts. Winters, Bamberger and Dickenson Capt Charles De F Chandler is attached to the Signal Corps now as disbursing officer but is available for aeronautical duty at any time. Of these officers, Lieut. Lahm has had the greatest experience and he and Capt Chandler are the two licensed pilots Lieut. Foulois made a record with the dirigible last year Winters, Bamberger, and Dickenson have each made a few flights in free balloons, but are still beginners in the art of aviation Major Squiers has made an exhaustive study of the theory of aviation of all kinds and is an authority on the subject, although his practical experience is limited to a couple of balloon and one aeroplane trips.

The equipment with which the Aeronautical Division has to work comprises a balloon house at Fort Myer and a balloon house of much greater capacity at Fort Omaha, where is also located a large electrolysis plant for the decomposition of water and the collection and storage of hydrogen, and the compression of it into steel tubes, for transportation The Aeronautical Division has a number of spherical balloons, one dirigible, and will have at least one and possibly two aeroplanes before another year being under contract to accept one from A. M Herring and the Wright brothers, each, if they can satisfy the tests and conditions laid down by the Signal Corps in their original specifications.

The present equipment of the Aeronautical Division is neither large nor strong, but while it is used almost entirely for experimental and training purposes it must not be supposed for a moment that it could not be used successfully in time of war The spherical balloons, which can be used either captive or free, are just as able to take an observer aloft in time of war and for photographic or observation purposes, as in time of peace to give him aeronautical experience The dirigible while a small one—ninety feet long—has not a very large radius of action Perhaps five hours in the air would represent its extreme of endurance. Yet it is perfectly efficient for the obtaining of information at a considerable distance.

The aeroplanes will be—one of them at least—the best of their kind in the world Mr Herring's machine is a mystery and no one knows whether it will be a success or not. But the Wright machine has demonstrated its efficiency

Nevertheless, much depends upon who will run an aeroplane—as to how it will behave. The selection of Lieuts. Lahm and Humphreys to be the first aeroplane pupils is a wise one, not only because these gentlemen have had more actual aeronautical experience than anyone else in the army, but because they are both of them the type of men to make a success of any enterprise requiring quick thinking and action and cool nerves.

Perhaps the most interesting thing in connection with army aeronautics which the United States has to show, is the large balloon house at Omaha, which is capable of housing a very large dirigible, several hundred feet long, and of supplying it with gas. Just as soon as Congress sees fit to provide the money, we can immediately build a large dirigible, without having to wait for a balloon house It is unquestionable that another and much larger balloon house, similar to or larger than the one at Omaha, will be erected at or near Washington. Indeed, Gen Allen has expressed himself in favor of building it big enough to hold a Zeppelin. Meanwhile, there is the plant at Omaha, ready for the big dirigible when we shall get it. At present it houses the small one. The filling of steel tubes of one cubic foot capacity with 1,000 cubic feet of gas is a regular part of the work at Omaha, so that these tubes, transported from place to place, can afford facilities for erecting and flying either spherical or the dirigible balloon. Hydrogen, of course, has so much greater lifting power than coal gas, that its use is dictated always except for balloons of large size which have not to carry much weight. The "No. 9," seen in the photograph, is capable of making a free flight with two men although it holds but 9,000 cubic feet of gas, which provides a gross lifting power of 630 pounds. The "No. 10," which has a capacity of 80,000 cubic feet, will lift more than a ton, filled with coal gas, and with hydrogen would lift 5,800 pounds. To have hydrogen easily and quickly available, any where at any time, is a great part of the work of the electrolysis and compressing plant at Omaha, and the possession of this plant, as well as of the various balloons, dirigibles, and aeroplanes, goes far to give the United States at least a start in aeronautics, whereas we are popularly conceded to be simply a minus quantity

---

The Testing of Intelligence.

BY OUR BERLIN CORRESPONDENT

The multiplicity and diversity of those intellectual forces which individually or collectively are called intelligence is only too often under-rated. In a recent memoir, R. Stransky draws attention to the error generally made in connection with scientific intelligence tests so called, by choosing a single aspect of mental life as representative of its totality It is a common mistake to mix up scientific training with intelligence, appreciating the mental capacity of a person according to the number and character of the notions assimilated at school and outside of it. Now, though a man, by frequently using abstract notions, gives evidence of a high intellectual capacity if these notions have been created by him, or at least acquired with a great deal of mental effort, those deriving the same notions from book reading do not necessarily show any productive superiority over lay people who have no occasion to deal with the same matters.

Generally speaking, it may be said that memory is by no means the only one, and still less, the most elevated of intellectual properties which, combined, make up the intelligence of a man Again, memory is of two different kinds, possessing different value, viz., either *impressive* or *associative*, according as this faculty relates to the more or less durable impressions left by our perceptions, or to the system of intellectual associations by which new perceptions are united to the existing associative elements. Now the former kind of memory obviously is far more primitive than the other, and cannot possibly be taken as a gage of intelligence. It is, in fact, generally known that adult persons, having assimilated a large amount of associative elements, are far from being so impressive as children, whose brains are as yet new Moreover, the most intelligent persons often forget the most rapidly and absolutely what they have learned at school in a purely mechanical manner, even though these matters belong to their special branch. A celebrated physician, Dr Billroth, has said in this connection that the "really educated people are just those who have forgotten more than others." The intelligence tests recently made in different countries on subjects chosen among the lower classes, have given especially instructive results in this connection by showing the frequently startling ignorance of the most common notions in the case of an individual perfectly capable by his mental capacities of earning his living and governing his house.

To this should be added that memory is only one of the different components of intelligence, and that judgment and power of combination are particularly important among the remaining functions of our intellect. Now, in appreciating the comparative mental forces of school children, this undeniable truth is only too frequently neglected, classification being merely based on the matters absorbed in a more or less superficial manner by the memory of the individual, and in everyday life we are unfortunately inclined to commit the same serious mistake.

In a previous memoir, the author has pointed out the individual diversity existing in the intellectual and psychical reaction to the outside world. There are thus individuals whose inner intellectual life, in its extraordinary wealth, cannot become fully evident, owing to a relative [illegible] of mental or [illegible] linguistic manifestation. Another group comprises those who have not always at their disposal a [illegible] rather extensive knowledge. These individuals [illegible] tranquillity and, generally speaking, [illegible] [illegible] knowledge is a [illegible] action, the [illegible] also [illegible] traversed by [illegible] there are [illegible] obstacles [illegible] the outside world as abundantly [illegible]

From what has been said will be understood [illegible] value may be ascribed to intelligence tests made according to a given scheme with [illegible] hand, and which mainly relate to memory, [illegible] of repartee, and adaptability of the [illegible]. It would certainly be interesting to test by a really [illegible] method also the mentality of those [illegible] individuals whose intellectual life consists of combination rather than reception. Some methods have already been suggested in this connection; the late Dr. Ebbinghaus thus endeavored to use as gage the faculty of supplementing words, and on this basis the author has developed the method of "word interpolation." However, all these methods, so far from showing the comparative value of intelligence, at most yield some information as to a given intellectual capacity

---

Artificial and Natural Ice.

Natural ice, domestic or imported from Norway, was used exclusively in France twenty years ago. At present, three-quarters of the ice used in France is artificial, although the importers of ice have gradually reduced their price one-half. In interior French cities artificial ice has completely supplanted imported ice. Fifteen years ago considerable quantities of Norwegian ice were still brought to Paris, via Dieppe. This commerce has now entirely ceased, and Norwegian ice is used only in cities on or near the seacoast. The annual consumption of ice for cooling purposes in France amounts to 800,000 tons, of which 150,000 tons are manufactured. 4,500,000 tons of ice are used annually in the United States.

A French writer has recently suggested the imposition of a tax upon imported ice, in order to protect the manufacture of pure and wholesome artificial ice. He reminds his readers that this industry is of French origin The French physicist La Hire first succeeded, in 1685, in freezing water by means of the heat absorbed when sal ammoniac is dissolved. In the nineteenth century another Frenchman, Bourgeois, constructed the first practical ice-making apparatus. In 1876 the method of transporting food in cold storage was created by Ch Tellier

Natural ice is not wholesome, as the majority of microbes survive temperatures of from —40 to —170 deg F Many sanitary casualties have been caused by the use of impure ice. An epidemic of typhoid fever in Rennes, in 1895, was traced to this cause.

In 1892, at the instigation of the Paris health board, the prefect of the Seine issued an ordinance which restricted the use of natural ice to industrial establishments and admitted as "edible" only artificial ice made either from sterilized water or water drawn from the city mains. Hence a protective duty of 6 francs per metric ton, or about $1.20 per ton, on imported natural ice is demanded.—Cosmos.

Official Meteorological Summary, New York, N. Y., October, 1909.

Atmospheric pressure. Highest, 30.59, lowest, 29.43; mean, 30.05. Temperature: Highest, 75; date, 9th, lowest, 35, date, 30th, mean of warmest day, 67, date, 8th, coolest day, 39; date, 29th; mean of maximum for the month, 59.8; mean of minimum, 46.7; absolute mean, 53.2; normal, 55.5; deficiency compared with the mean of 39 years, 2.3. Warmest mean temperature of October, 61, in 1900; coldest mean, 50, in 1876. Absolute maximum and minimum of October for 39 years, 88 and 31. Average daily excess since January 1st, 0.7 Precipitation: 0.74; greatest in 24 hours, 0.31; date, 23rd; average for October for 39 years, 3.36. Accumulated deficiency since January 1st, 8.84. Greatest precipitation, 11.56, in 1903, least, 0.12, in 1879 Wind: Prevailing direction, west; total movement, 9,396 miles; average hourly velocity, 12.6; maximum velocity, 46 miles per hour. Weather: Clear days, 16; partly cloudy, 8; cloudy, 5; on which 0.01 or more of precipitation occurred, 5. Thunderstorms, 23rd. Frost, heavy, 20th, 21st, 30th. Fog, dense, [illegible]

An Inventors' Exhibition.

The Royal Württemberg Chamber of Commerce is organizing a State exhibition of inventors' models to be held next year at Stuttgart. Its chief purpose is to help poor inventors who have little opportunity of bringing their inventions under the notice of likely purchasers. The directors of the society promise that strict impartiality will be observed in the selection of exhibits, and that none will be [illegible] worthy of serious consideration [illegible]

[illegible]

[illegible] it occurs to [illegible] main springs may be be[illegible] properly finished; that is, be[illegible] short or small pieces on the edge that [illegible] and rounded on the edge since [illegible] liability of cracks in band [illegible] it is necessary to finish the edges. The [illegible] in the springs break only at the edges, and I [illegible] a more perfectly finished edge.

[illegible] J. H. Mi[illegible]

[illegible] AND THE BREAKING OF WATCH SPRINGS.

To the Editor of the Scientific American

[illegible] the subject of breakage of main springs, allow me to contribute the following:

Every watchmaker has observed that at certain times a large part of his repair work consists of replacing broken main springs. And it is often observed that the spring is broken into as many parts as there were coils in the spring, and sometimes a fracture occurs every half coil.

The writer on one occasion, while wondering at the appearance of a spring broken up into half coils, noticed that the pieces were magnetized, and made a simple experiment of determining the polarity of the pieces by bringing the fractured ends together. He discovered that when the pieces were fitted together as they were in the original spring, the ends of the pieces at each joint were of like polarity. He then suspended a small soft-iron indicator from a single fiber of silk in a small material bottle, and by passing this indicator along the line of broken pieces of spring, discovered that the points of fracture were of alternate polarity. This was puzzling, for the ends of the pieces at each point of fracture should be of opposite polarity.

The writer has since caused a spring to be magnetized while coiled in a watch barrel, and on extending the spring found the points of polarity fixed in the spring, alternating every half coil.

Now it is evident that the repulsive force of like polarity at a point in each half coil has somewhat to do with the breaking of the spring.

When we consider that many springs, when wound up, are strained almost to the point of breaking, if we then subject them to the magnetic strain, the breaking as described does not seem so strange.

Jersey City, N J FRANK G BURCH

THE RENAISSANCE CLERGY AND SCIENCE.

To the Editor of the Scientific American

The mention of the supposed papal bull against Halley's comet at its appearance in 1456 naturally suggests the consideration of the scientific work of that time. The universities were all in the hands of the ecclesiastics. In Italy particularly practically all of the professors were clergymen. In spite of the usual impression with regard to church opposition to science, this is a great period in the history of science. Though it is not usually realized, the Renaissance affected science quite as much as it did arts and letters. During the century from 1450 to 1550 the foundation of much of our modern science was laid. In the Archives of Diagnosis (New York, April, 1909) I called attention to the fact that to a man of this period, the famous Cardinal Nicholas of Cusa, we owe the first hint as to the use of accurate methods in diagnosis in medicine. There were no watches, for the "Nuremberg eggs" were not made until the next century, and the taking of the pulse had been very indefinite. Cardinal Nicholas suggested that the amount of water passing through a water clock during one hundred beats of the pulse should be weighed, and compared with the amount of water that flowed through standard water clocks, in normal and abnormal cases of various kinds. He suggested that the same thing should be done for the respirations. He also declared that specific gravity in the study of the urine and blood would surely be of value. Prof. Karl [illegible] of the University of Bonn called attention to this some five years ago in the Berlin Medical Journal.

It seems surprising at first that such thoroughly scientific suggestions for medicine should have come at the middle of the fifteenth century. A review of the scientific situation during the latter half of the century, however, showed how natural they were. Cardinal Nicholas himself wrote a series of books on mathematics. It is in one of these on mechanics that his suggestion with regard to medicine occurs, and he touched many other important scientific questions. He declared the doctrine that the earth cannot be fixed, [illegible] He denies that it [illegible] [illegible] a whole chapter to algebra. His greatest contemporary was Regiomontanus, the father of modern astronomy. Regiomontanus introduced the use of the tangent into mathematics. He was invited to Rome by the successor of that Pope Calixtus who is said to have issued the bull against the comet, to become the papal astronomer. Cantor gives him a very important place in the history of mathematics. Antonius the Archbishop of Florence was another contemporary, and his monograph on comets contains a number of interesting anticipations of ideas that did not get into astronomy until after Galileo's time. Galileo was rather inclined to think comets appearances in our atmosphere. Antonius thought them far distant. At this time Puerbach was teaching mathematics and astronomy at Vienna, and translating the Alexandrian mathematicians and astronomers from Greek into Latin for the universities of that time. A little later Novara was doing the same thing at Padua. When Copernicus, having completed his studies at Cracow, wanted to do graduate work in astronomy and mathematics, he went down to Italy. Before the end of the fifteenth century he announced his new theory of the universe. Within the same decade Columbus gave the men of his time a new world, and Copernicus what his bishop friend Ferber declared to be a new universe.

Medicine woke up as the result of the touch with old Greek medicine, just as mathematics and astronomy did. Italy was the home of graduate teaching in this as in all the other sciences. Linacre and Caius and Free from England went down to Italy to study anatomy and clinical medicine. Berengarius was teaching at Bologna, Benivieni at Florence, and Leonicenus at Vicenza, and modern medicine was receiving a great new impetus. During the century from 1450 to 1550, the Renaissance century (which we Americans should call Columbus's century) all our modern anatomy came into being. The work on it was all done in the ecclesiastically ruled universities of Italy. Vesalius, Varolius, Columbus the anatomist, Eustachius, Caesalpinus, and Piccolomini, with Fallopius and many others, did their work in the peninsula. Most of them were professors of anatomy at Rome. Eustachius, whose name is attached to several structures in the human body, Columbus, who discovered the circulation in the lungs, Caesalpinus, who first described the circulation of the blood in the body, and Varolius, after whom important structures in the brain are named, were all papal physicians. Chemistry and pharmacology woke up in the persons of the monk Basil Valentine and his great successor Paracelsus.

To think of the latter half of the fifteenth century as a time when there was lack of interest in science or any suppression of scientific aspirations, is to be ridiculously ignorant of what actually occurred, for the chapter of the Renaissance of science when the Greek masters were rediscovered and translated for the modern world is quite as important as the story of humanism or the new learning, when the Greek literary texts touched the genius of the modern world to that outburst of new thought that made one of the most interesting periods in the world's history. A little more study of science history, and not of the supposed religious history of the time shows how utterly without foundation is the squabbling over religious intolerance.

A New Nitrous Product.

At Mülhausen, Alsace, there is being manufactured a new nitrous product for use as fertiliser, in the shape of a nitride of aluminium, the combination of nitrogen and aluminium being obtained by a new process invented by M Serpek. The inventor first studied the preparation of carbide of aluminium which he obtained in the form of yellow crystals by heating a mixture of alumina and carbon in the electric furnace. This carbide, like the other carbides with which we are acquainted, has the property of fixing gaseous nitrogen and thus gives nitride of aluminium. To obtain an economical production of this latter, he does not isolate the carbide of aluminium, but after the formation of this body in the electric furnace it is at once mixed with a fresh quantity of alumina and is then treated with nitrogen gas. He thus obtains masses which contain 20 to 24 per cent of nitrogen, and this can be used at once as fertiliser. Under the influence of atmospheric oxygen and moisture we have ammonia given off, which is transformed by bacteria into nitrates and alumina. The inventor is working the new process in a small factory which he installed, and has realized some interesting results during the last year. He now produces crystallized nitride of aluminium which has a high percentage of nitrogen—as much as 24 per cent. An advantage of his process is that we do not need to use pure nitrogen which requires an expensive plant of Linde or other machines, but the gas from the producer is employed, this containing 77 per cent of nitrogen and 23 per cent carbon monoxide with a little carbonic acid. Thus we have a very simple and rapid process for the crystallized nitride, and owing to the various advantages, it may compete with cyanamide.

The Migrations of Mackerel and Herring.

Although the mackerel fishing season usually ends in October, thousands of mackerel have been caught after October in recent years in the English Channel. In November, 1901, a bank was discovered which often yielded a catch of six tons in two or three hours. Several similar winter assembling places have since been discovered. It had previously been assumed that mackerel seek the North Atlantic in winter, and return in spring to the North Sea and the coasts of Cornwall and Brittany, but these new discoveries indicate that they do not migrate but simply seek greater depths in the same locality for their winter resting places, where they remain assembled during the day. At night they disperse in search of food and are consequently seldom caught in the nets.

Localized schools of herring have also been discovered in recent years. There may be migratory schools as well, observes Prometheus, but it appears certain that the herring is a more sessile fish than has hitherto been assumed. During its first year or until it attains a length of 4 or 5 inches and probably until its length has increased to 8 or 9 inches, at the end of the second year, it remains near the place of its birth. After the second year it begins to appear sporadically. At all seasons the waters of the English Channel contain adult herring which are evidently of the same breed with the young fry of spring. Even in winter a few herring are caught but only at great depths, although large numbers are caught near the surface in summer. The assumed migration of herring to Arctic waters is made doubtful by the discovery of these sessile schools. This discovery also explains the existence of the distinct local races which are recognized by the fishermen, and which always reappear on the same fishing grounds at the breeding season.

"Cork Metal"

BY F J WILLOTT

At one of the recent aeronautical exhibitions samples of a metal were shown under the name of "cork metal," which was said to be 40 per cent lighter than aluminium, and to have numerous other properties which should make it a rival of the latter.

Great secrecy was maintained as to the nature of this wonderful metal, but its properties were such as to rouse my interest, as a consequence of which I have submitted it to chemical analysis.

In appearance the metal resembles very strongly the alloys known as magnalium. The surface presents a lusterless whitish gray color, both sheets and bars showing the scorings and scratches so frequently found on badly rolled or drawn aluminium. Careful analysis gave the following result:

Aluminium	0 04	per cent
Iron	0 017	per cent
Zinc	0 48	per cent
Sodium	0 21	per cent
Magnesium	99 30	per cent

It will be seen therefore that essentially "cork metal" is nothing but magnesium to which a small amount of zinc has been added. Whether this latter has been purposely introduced or, as is more probable, is merely present as an impurity I am unable to say.

As the metal evolves hydrogen when immersed in water, I found it necessary to use organic solvents for the determination of the specific gravity. In alcohol this was found to be 1 762, thus confirming the conclusion that cork metal is, in fact, magnesium.—Chemical News.

The Current Supplement.

Of the two chief constituents of the atmosphere, we have hitherto been accustomed to look upon oxygen as the fundamentally important element. Nitrogen however is of vital importance, so important in fact that the task of finding out and opening up new sources of nitrogen compounds has become one of the most interesting and pressing problems of the day. The subject is well discussed in the current SUPPLEMENT, No. 1767 by Mr A. Bernthsen. The Schneider torpedo-testing station is elaborately described and illustrated. Mr Snowden B Redfield describes the making of automobile tires. The stars are due to fall on the nights of November 12th to 14th a fixture in the celestial schedule of events. The display is called the Leonid shower, and is discussed in the current SUPPLEMENT. A new gas-electric motor car for the Third Avenue Railway Company of New York city is illustrated. The article on the Paris Aviation Exhibition is concluded. The usual engineering notes, electrical notes, and trade notes will be found in their accustomed places.

MAKING ALCOHOL FROM WOOD WASTE

A middle West industry for which a great future is promised is that of the manufacture of alcohol from sawdust shavings slabs and other refuse of the lumber mill

Rumors of improved methods and great economies in the manufacture of wood alcohol have been in the air for some time and we have received a number of inquiries on the subject from subscribers and correspondents We are glad therefore to be able to give now some details of the new process for which patents have recently been granted to Mr Malcolm F Ewen and Mr George H Tomlinson of Chicago.

It has long been known that ethyl alcohol and other valuable by products could be made from wood waste in laboratory experiments and many processes have been developed but practically none of them has reached the stage of economic success on a commercial scale

One of them aroused the interest of Mr John M Ewen better known as a constructional steel work engineer and manager of the Fuller Construction Company builders of so many skyscrapers Although it was not found practicable commercially Mr Ewen was so much impressed with the possibilities of cheap alcohol from wood waste that he spared enough time and energy from his other great responsibilities to continue independent investigations, and it is largely owing to his personal and financial support that the present successful process has been developed, one of the patentees being his brother

Lumbermen have long been alive to the necessity of finding a use for the appalling piles of waste they are compelled annually to destroy if only as a means of additional profit before the question of conservation of natural resources became of national interest In addition there are many and various uses to which alcohol is applicable with advantage and from which it has hitherto been excluded by its cost

All kinds of internal-combustion engines for instance can use alcohol as fuel with advantage over gasoline and with very little modification

One of the greatest advantages of the production of a pure alcohol from wood however will be the release for food purposes of the millions of bushels of corn and barley now consumed in the manufacture of grain alcohol

The price of grain alcohol is at present $2 60 a gallon at 188 proof of which $2 07 is internal revenue tax the net wholesale price being only 53 cents Corn worth 26 cents is required for the manufacture of a

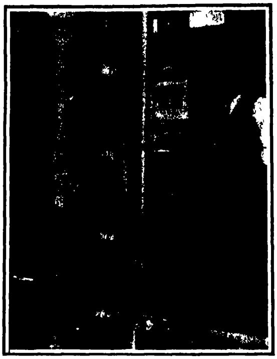
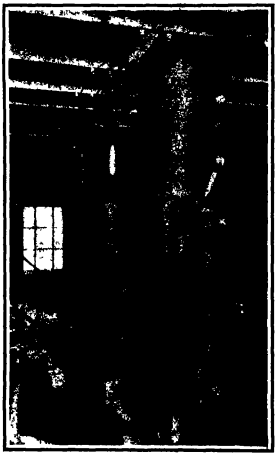
A diffusing battery of four units.



Reading the thermometers.

One of the large tanks in which the wood pulp is fermented.

The digesting machine which performs the functions of a mechanical stomach. It converts the starch of wood waste into sugar



Still by which a fine grade of ethyl or grain alcohol has been made out of sawdust and slabs

MAKING ALCOHOL FROM WOOD WASTE.

TRIALS OF THE NEW "DREADNOUGHT"—"NORTH DAKOTA."

In view of the fact that the first two "Dreadnoughts" to be built for the United States navy are identical in everything except motive power, the "Delaware" being driven by reciprocating engines and the "North Dakota" by Curtis turbines, an unusual amount of interest has been aroused by the recent speed trials of these two ships The "Delaware," which was built by the Newport News Shipbuilding Company, was tried out over the course off Rockland, Maine She is equipped with Babcock & Wilcox boilers, and in the five trial runs for standardization of her propellers, which were made over the mile course, she developed a maximum speed for one mile of 21 98 knots, a mean speed for the five runs of 21 44 knots, a maximum horse-power of 30 000, and a mean horse-power of 28 578

The "North Dakota" is not only an exact duplicate of the "Delaware" in the form of her hull and in the displacement but in common with that ship is equipped with fourteen Babcock & Wilcox boilers. Consequently, the Navy Department was in a position to make a most exact comparison of the efficiency of the respective motive power all the conditions except

(*Continued on page 360*)

Length, 518 feet, 9 inches. **Beam,** 85 feet, 2½ inches. **Mean draft,** 27 feet. **Displacement on trial,** 20,000 tons. **Speed on trial,** 21 86 knots. **Horse-power,** 33,875. **Coal supply,** 2,500 tons. **Armor:** Main belt, 10 inches to 12 inches and 7 feet 6 inches wide upper belt, 10 inches to 8 inches and 8 feet wide, barbettes and turrets, 11 inches. **Armament:** ten 12-inch forty-five caliber guns fourteen 5-inch fifty-caliber guns.

UNITED STATES BATTLESHIP "NORTH DAKOTA", FASTEST "DREADNOUGHT" AFLOAT

The Wright Brothers and Their First American Pupils.

On November 4th Orville Wright arrived at New York fresh from his exhibition flights at Berlin and at Potsdam before the Emperor and Empress. During his stay he taught several army officers how to operate his biplane These machines are now being manufactured in Germany, England, France and Italy, and a large company is about to be organised to make them in the United States.

Wilbur Wright has finished teaching Lieuts. Lahm and Humphreys the operation of the new government biplane at College Park, Md The aerodrome is located beside the tracks of the B & O Railroad, some eight miles from Washington and in the course of the lessons the aeroplane had several brushes with the express trains all of which it is reported to have won easily An important modification was made a month ago by Wilbur Wright. This consisted in removing the upper surface of the front horizontal rudder and rigging it just in front of the rear vertical rudders as a tail It is said to make the machine much easier to control and also that it does away to a large extent with pitching Orville Wright changed in a similar manner the machine that he used in Germany

After being taught for a fortnight how to operate the government biplane Lieuts Lahm and Humphreys on October 26th made their first flights in it alone Lieut Humphreys made the first flight, which consisted of two circuits of the field, in 3 minutes. Lieut Lahm next flew six times around and described some small circles as well his time being 13 minutes. Lieut Humphreys then made another flight of 8 minutes On October 30th both officers had been flying for 10 minutes when the gear that drives the magneto dropped off causing the engine to stop The machine glided safely to earth On November 1st after making an excellent 16-minute flight Lieut Lahm remained aloft 58½ minutes Two days later Lieut Humphreys with Lieut Foulois as passenger, flew 61¾ minutes and came within 10¼ minutes of equaling Orville Wright's record flight with a passenger Lieut Lahm after one false start succeeded in making an 8¾ minute flight with Lieut Sweet who weighs 185 pounds and whom Wilbur Wright had twice tried to take up in a calm without accomplishing it Lieuts Humphreys and Foulois made another flight of 25 minutes. On November 5th when Lieuts Lahm and Humphreys were making a flight early in the morning the motor began missing and the machine got dangerously near the ground The end of the lower plane struck in making a turn and the machine was rather badly smashed, although neither of its occupants was hurt

◆

An Electrolytic Scrap Tin Process.

The electrolytic method for extracting tin from scrap is quite extensively used in Italy at the present time An alkaline bath is used in most of the factories For the anode tin scrap is used while the cathode is made up of plates of iron The bath is a soda lye which is kept at a high temperature Oxidation of the tin at the positive pole produces stannic acid which is transformed to stannate of soda by combination with the soda of the bath This stannate of soda is reduced at the negative pole and here the tin is deposited Soda is re-formed in this way

Considered theoretically the electrolysis should have the effect only of depositing the tin at the negative pole, while leaving iron at the positive pole, the liquid of the bath not changing in composition and no gas being given off at the electrodes It was found however that a heating of the bath gave a much better result which is explained by the lowering of the electrical resistance when the temperature rises and by the greater solubility of the stannic acid in the caustic soda at high temperatures Thus in order to facilitate the chemical and electrolytic phenomena the liquid is heated and given a rapid circulation in the direction of the current The reactions are easily produced at the positive pole owing to the great surface of contact of the anode and the bath but such reactions are less easily produced at the cathode whose surface is much smaller Therefore at the beginning of the operation there is formed an excess of stannate of soda and its quantity keeps on increasing When the percentage of stannate exceeds a certain value determined by experience the bath is not sufficiently alkaline to allow of the good progress of the actions Some of the liquid is then removed and replaced by soda lye When the operation is well carried out there is but little hydrogen set free at the negative pole and nearly all the oxygen enters into reaction at the positive pole The amount of gas given off shows an indication as to the working of the process and the end of the extraction of the tin coincides with the greatest disengagement of gas.

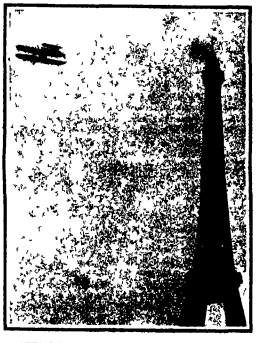
In Italy the tanks generally used are made of iron and have about 100 cubic feet capacity The liquid is made to circulate rapidly between the re-heater and the tanks by a pump The six anodes which are used are formed by perforated iron holders containing the tin scrap, while the seven cathodes are made of plates of iron. The tin is thrown down on the cathodes in a spongy state which adheres but slightly and can be collected by scraping off. The powder thus secured is washed and then compressed in cylindrical cakes, which are kept under water in order to prevent oxidation. The cakes are melted in a furnace of the kind which is used for bismuth A part of the tin is oxidised during the operation The metal is then recuperated by a reducing treatment of this oxide in a reverberatory furnace.

The iron obtained at the cathode does not contain more than 0.1 per cent of tin when the process is well carried out, and this iron is of a very good quality and is sought for by iron works. It is this part of the process which makes the present method of tin extracting economical, for unless the iron can be used in metallurgy the case would be otherwise, as is true for other tin extraction methods. The stannate of soda taken from the bath is then transformed to bioxide of tin, and to carry this out we filter the liquid taken from the tanks and a current of carbonic-acid gas is passed through it. There is formed thus carbonate of soda and stannic acid, and this latter is roasted so as to give bioxide of tin, this product being used in ceramics and also in the chemical industry for manufacture of tin salts At present there is used in Italy from 50 000 to 60,000 tons of tin, the greater part of which goes to the manufacture of tin cans. The scrap is estimated at 11 000 tons. As soon as the new works are completed, the whole of this amount of scrap can be treated in Italy

◆

THE RECORD FLIGHTS OF COUNT DE LAMBERT AND HENRY FARMAN

Mention has already been made in these columns of the magnificent flight of Count de Lambert on a Wright biplane from the Juvisy aerodrome to Paris and above the Eiffel Tower In the present issue we reproduce a photograph showing the aeroplane flying near the tower at a high elevation After circling about the aerodrome a couple of times in order to reach a height of some 450 feet, Count de Lambert left it at 4 37 P M on October 18th and flew straight for Paris, passing over Chevilly and Villejuif and entering the city by passing over bastion 81, about 180 feet to the left of the Arcueil gate. From this point he curved to the left and kept steadily ascending, so that when he reached the Eiffel Tower he was at a height of some 400 meters (1,312 feet), or 100 meters (328 feet) above the top of this lofty edifice. After passing over it he described a wide semi-circle, and returned to Juvisy along the same route He alighted at 5 30 P M less than a score of feet from his shed, and was heartily cheered by the crowd of spectators who had witnessed his departure and return. The total length of the flight was 49 minutes 39 seconds, and the distance covered close to 30 miles. The air-line distance from the aerodrome to the tower is about 12½ miles, but the course followed by Count de Lambert was a couple of miles longer, to which must be added the circuits of the aerodrome at the start and upon the return When congratulated upon his magnificent performance by Orville Wright (who had just arrived from Berlin), Count de Lambert was very modest and had but little to say. The chief impression was the slow speed at which he seemed to be traveling when flying at a great height, and the well-nigh interminable time before he finally reached again his starting point. Although his flight was one of the most daring that has [illegible] Count did not make it as [illegible] while it marked big [illegible] by that in aviation it stands [illegible] purpose. Although Farman's new [illegible] made at Mourmelon November 3rd, [illegible] more importance from a practical point of view.



COUNT DE LAMBERT FLYING NEAR THE EIFFEL TOWER.

While competing for the Michelin trophy last [illegible] Wednesday, Farman flew continuously for 4 hours, 6 minutes, and 25 seconds, during which time he covered 232 kilometers (144 miles) at an average speed of 35.08 miles an hour Thus he has actually covered in a single flight a distance as great as that from New York to Albany, which we stated some time ago we believed him capable of covering if he had seen fit to revisit America and participate in the contest held during the Hudson-Fulton Celebration. This contest, which is for a prize of $10,000 for the first aeroplane or dirigible that flies from New York to Albany, is to be held open until October 9th, 1910.

The motor used by Farman in his latest record-breaking flight is the same one that he used in winning the long-distance contest at Rheims. It is a Gnome revolving-cylinder motor of 50 horse-power, having 7 cylinders that revolve in a vertical plane around a stationary crankshaft. In a brake test made by the Aero Club of France, this motor developed only 34 horse-power and ran for 3½ hours; Farman has had however, greater success with it, as evidenced by his excellent flight. Both Paulhan and Sommer, as well as Farman, have also made excellent flights recently upon Farman biplanes at the recent aviation meetings at Blackpool and Doncaster in England The revolving-cylinder motor seems to have worked well in every instance, and to have demonstrated its reliability

The Michelin trophy was brought to America last week by the president of the Aero Club of America as a result of Wilbur Wright's flight of 2 hours 20 minutes on December 31st last at Le Mans. When asked whether he thought it would remain here, Wilbur Wright is said to have replied that the winner for this year must be prepared to fly from dawn till dark, so in all probability Farman's record will be considerably beaten before the year is out.

As the trophy can only be competed for between 10 A. M. and sunset, however, if the flight for it is not made until the last day of the year, it cannot be of more than of six or seven hours' duration.

◆

Disinfectants in Water Purification.

At the annual meeting of the New England Water Works Association one paper dealt with the extensive studies which have been in progress for some years at the Laurence Experimental Station, and another recorded some interesting results obtained at the Poughkeepsie water works. At the Laurence establishment many disinfectants have been tested, including copper salts, permanganate of potash, and calcium chloride. Unlike copper salts, both of the latter reagents are rapidly decomposed, they effect a considerable reduction in the number of bacteria present, and the resulting compounds are of harmless character from the physiological standpoint. Recent experience at Poughkeepsie relates chiefly to the employment of calcium chloride, which has been found beneficial in preparing the water for filtration The general tendency to-day in water purification is toward reduction of the work to be performed in filters. British endeavors of this class are mainly confined to the provision of storage reservoirs where partial purification occurs by natural agencies, while American engineers more generally attempt to hasten the process by means of coagulants and disinfectants alone or in combination. The papers mentioned are worthy of consideration, but we think the British method of preliminary treatment generally preferable, especially for waters already characterized by a fairly large proportion of mineral salts.

◆

The Russian Secret Service and Aeronautics.

The Russian government views with alarm the advent of the airship or aeroplane. Evidently the fear that some aeronautic nihilist may possibly drop a bomb upon the Czar's palace has wrought up the government to a pitch of nervous fear The Minister of the Interior has given the following instructions to his subordinates

1. All ascents of flying machines and airships are to be carefully watched by the police

2. All the aero-clubs of Russia must be registered, and their members are subject to supervision by the secret police.

◆

A good example of the economy often accomplished by chemical investigation and discovery is furnished in the case of ultramarine. Many years ago when this was made by powdering the mineral lapis lazuli, it sold for more than its weight in gold. Now that the chemist has discovered how to make the same material from such cheap substances as kaolin, [illegible] and carbonate, charcoal, sulphur and [illegible] only a few cents per pound [illegible]

A SIMPLE METHOD OF LAYING OUT A SUN DIAL.

BY S. WILLARD BROWN.

The sun is a very poor timekeeper At this time of the year it is about a quarter of an hour fast, while in February it will be nearly fifteen minutes slow For this reason we do not take time from the real sun, but from an imaginary sun which comes to meridian every twenty-four hours exactly on the second. There are only four days in the year when the real sun is on time, viz., April 15th, June 15th, September 1st, and December 25th A sun dial records the real sun's time and not the mean sun's time, and consequently is a very poor timepiece for actual service in these days. However, it makes a very attractive ornament, and readers of Handy Man's Workshop may find it interesting to make a simple dial. It is popularly supposed that the laying out of the sun dial face is a difficult matter, but this can be done without the use of mathematics if the difference between the real solar time, the mean solar time, and standard time is clearly understood Noon, strictly speaking, is the moment when the sun comes to meridian, that is, when it is due south of the observer As we have just stated, if we depended upon the real sun to mark the noon hour, some of our days would be shorter than others. Our watches would have to run anywhere up to thirty seconds a day fast and slow at different times of the year, in order to keep pace with the real sun. The imaginary sun which keeps perfect time is not much better for general purposes because noon would be different to different observers. A man in New York would have different time from a man in Brooklyn. A commuter from the Oranges would have to set his watch ahead about a minute when going to business and back a minute when returning home. To avoid all this complication we take our time from the mean noon at certain fixed meridians just 15 degrees apart. The eastern section of the country gets its time from noon at the seventy-fifth meridian west of Greenwich, central time is taken from noon at the ninetieth meridian, mountain time, from the hundred-and fifth meridian, and Pacific time from the hundred-and-twentieth meridian west of Greenwich Bearing these facts in mind, we can proceed to lay out our dial without the use of mathematics on the four days above referred to when the real sun and the imaginary sun come to meridian at the same time.

Fig. 1 —A SUN DIAL FOR USE AT THE NORTH POLE.

First of all, it is absolutely necessary that the line casting the shadow on the dial face shall be absolutely parallel with the axis of the earth. This being the case, it makes no difference what the position or form of the surface receiving the shadow may be so long as it is rigid. Our problem resolves itself therefore into the question of how we shall provide for the placing of this shadow-casting line.

It is perfectly apparent that at the North Pole this line would occupy merely an upright position, and a dial for such a situation would be similar to Fig. 1. At the southern extremity of the earth's axis a similar instrument would be required, except that the hour marks would have to number round in the opposite direction

At the equator an apparatus similar to Fig. 2 has been devised. If the shadow-casting line is to be parallel to the earth's axis, it is evident that at this point it must be perfectly horizontal and pointing north and south. Just here it may be of interest to call attention to the fact that at the equator the sun always rises and sets at six o'clock. The most convenient surface to receive the shadow from a line placed as above described would be the interior of a half cylinder, and if this were equally distant at all points from said line, the hour marks would be twelve equal divisions of its surface. This same form of sun-dial could be used at any latitude, provided it has an arrangement for canting it up (Fig. 3) so as to maintain the position of the axis line parallel with the earth's axis.

In latitudes midway between the equator and the poles a horizontal form of sun-dial is most commonly used, and we will construct ours according to that model.

Fig. 4 affords a general idea of the method of construction. The material should be well-seasoned pine for the baseboard which may consist of two pieces of ¾ inch stock measuring 10½ by 6 inches each with two 12-inch cleats to correspond In the preparation of the gnomon or shadow-casting piece *A B C*, the essential feature is that the angle at *B* shall invariably correspond in degree with the latitude of the locality where the dial is to be placed For instance, since Boston is 42 deg. 21 min. north latitude, angle *B*, if the dial is to be used in Boston must be a shade over 42 1/3 degrees, at New York the angle *B* should be 40 3/4 degrees.

Fig 2.—A SUN DIAL SUITABLE FOR USE AT THE EQUATOR.

The base line of the gnomon should be at least long enough to extend two-thirds of the way across the board. If our dial is to be for indoor use only the shadow piece may be constructed of heavy bookbinder's pasteboard, but for outdoor exposure it had better be made of brass or heavy galvanized sheet iron Make a paper pattern, and get your tinsmith to cut it out for you. The out-of-door sun dial should receive at least three good coats of the best white lead paint as a protection from the weather

Having reached this point and having assembled the various parts, fastening them securely in place with screws or good wire nails we are now ready to make our markings upon the dial surface for the twelve or fourteen hours of daylight during which our sunshine clock will be of service These may be made temporarily with lead pencil and afterward lined in with waterproof ink or good black paint.

It is very essential while placing these lines of course, that the dial shall remain in an absolutely fixed position and that the gnomon shall point exactly north and south, as it ought always to do if our time is to be at all accurate Now, without a surveyor's compass how shall we accomplish this? Mean solar noon in Boston is at sixteen minutes of twelve o'clock. By that we mean that at 11 44 the imaginary sun is directly in the south and if at noon on Christmas day or any other of the four days above mentioned when the imaginary and real suns coincide we place our dial so that the gnomon with angle *B* toward the south, casts at either side no shadow whatever, the shadow that extends from the edge of the gnomon marks the hour of XII At 12 44 a line drawn along the shadow will be the I o'clock mark of the real solar time. With a reliable timepiece in hand we may thus proceed to make the necessary markings as the hours go by, being careful of course to see that the position of the instrument has not been altered The morning hours will bear the same relative distances from XII on the opposite side of the dial.

Fig 3.—A CONVEX DIAL TILTED TO THE ANGLE OF ITS LATITUDE.

To find the difference between mean solar time and the standard time for any locality apply the following rule Ascertain the difference in longitude between the given place and the meridian of the standard time of that locality as indicated by the following table

Colonial time is mean solar time of 60th meridian
Eastern time is mean solar time of 75th meridian
Central time is mean solar time of 90th meridian
Mountain time is mean solar time of 105th meridian
Pacific time is mean solar time of 120th meridian

Multiply the number of degrees of difference in longitude by four and the result will be the difference of time in minutes.

If the standard meridian is the larger of the two, mean solar noon will occur just as many minutes before 12 o clock standard time If it be smaller, the time will be so many minutes later

To illustrate

The meridian of eastern time is 75 deg
Longitude of Boston is 71 } deg
———
4 deg
Multiply by 4
———
16 minutes.

The meridian of eastern time being the *larger* therefore mean solar noon will occur at 16 minutes *before* 12 o clock and the sun dial must be placed so that the gnomon casts no shadow at that time

Should it be thought desirable to construct a vertical sun dial to be attached to the southern wall of a house, for instance the same principles apply as we have already laid down, only be sure to bear in mind that the essential angle of the triangular gnomon is always the one farthest to the south and not the one resting against the baseboard It is more than probable that the wall to which the dial is to be fastened does not face exactly south so that it will be necessary to bend the gnomon slightly to the east or west, in order to get the proper direction for its upper edge

Having had good success in the construction of one or more sun dials made according to the foregoing suggestions, possibly it may be thought desirable to construct something of a more permanent nature, and the following directions in regard to the use of concrete for that purpose may be of service

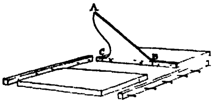


Fig 4.—CONSTRUCTION OF A HORIZONTAL DIAL.

In making a mold for the construction of the plane portion of the dial one of two methods may be followed Make a shallow box the exact size and shape of this part of the dial. Before the bottom board is fastened on, draft upon its interior surface a reversed tracing of the markings of a previously constructed dial giving of course also the hour-mark figures These may now be gone over with a V-shaped chisel if raised markings are desired or they may be built up with modeler's wax if figures indented in the stone surface are thought to be more desirable A thin but tapering piece of board should be fastened at the point where the gnomon is to be inserted later on The entire mold should now be thoroughly gone over with tallow to prevent the concrete mixture from sticking at any point

A good concrete for our purpose may be made of two parts sand and one of Portland cement These should be thoroughly mixed before water is added About 20 per cent of water is supposed to be about the right proportion to use but a better rule to follow is to continue to add water until the mixture has such a consistency that tapping upon it with a fl trowel will bring water to the surface The concrete should be allowed to set for five or six hours before the mold boards are removed and by the way these should have been fastened together with screws After this the stone should be kept moistened every hour or two for two or three days to obtain the best results Another method of making this part of the dial though the result might not be quite satisfactory would be to fill a shallow box with concrete working the markings into the surface before it has begun to set very much

The gnomon may be made of iron by your blacksmith neighbor in which case it ought to undergo some treatment to prevent its rusting or it may be cast of brass from a wooden model Having this firmly cemented in the groove provided for it we have now a dial ready for whatever surroundings may seem desirable Concrete stone may be rendered impervious to the action of water or frost by the following treatment First wash it thoroughly with a hot solu tion of Castile soap, and after rubbing in and drying, apply a solution of alum.

Since the color of the concrete may not be wholly satisfactory for receiving the shadow of the sun, the upper surface of our stone may be kept painted with lead paint or with an insoluble whitewash

◆

EXPERIMENTAL COLOR MAKING WITH SIMPLE CHEMICAL SOLUTIONS.

BY A J JARMAN

Color manufacturing to-day is carried out upon a very large scale, and so cheaply that it has often been considered quite impracticable for the amateur to prepare his own colors but one should bear in mind that the colors so produced are of absolute purity containing no adulteration whatever Furthermore, there is not only an elementary knowledge of chemistry obtained but a useful and valuable product, at the cost of a very small outlay

The following colors can be easily made without the use of special chemical vessels the one essential point being that all the water used should be filtered so as to free it from organic matter and mechanical impurities in the form of iron rust and sometimes small fragments of carbonate of lead obtained from the lead supply piping

The following solutions must be made in clean glass bottles, half a dozen strips of glass half an inch wide and ten inches long and half a dozen or more of common glass tumblers and a few sheets of white blotting paper

In the clean bottles make up the following chemical solutions

1 Iodide of potassium 120 grains dissolved in 10 ounces of water a label being placed thereon with the name of the chemical

2 Bichloride of mercury, 120 grains dissolved in 10 ounces of hot water and allowed to become cold

3 Two drachms of nitrate or acetate of lead dissolved in 10 ounces of hot water

4 Half an ounce of protosulphate of iron dissolved in 10 ounces of water

5 Half an ounce of ferricyanide of potassium (*red prussiate of potash*), also dissolved in 10 ounces of water

6 Half an ounce of bicarbonate of soda dissolved in 10 ounces of water

7 Two drachms of nitrate of silver dissolved in 10 ounces of distilled water

8 Half an ounce of bichromate of potash dissolved in 10 ounces of water

Now having all these chemical solutions made proceed as follows Pour into one of the tumblers two or three ounces of the bichloride of mercury solution, then add carefully half an ounce of the iodide of potassium solution, stir well with one of the glass strips when instantly a beautiful deposit of scarlet vermilion will be formed

Be careful not to add too much iodide solution because this scarlet vermilion is soluble in a solution of iodide of potassium which may become partially or wholly re-dissolved If this is the case continue to add more of the bichloride of mercury solution when the precipitate will return Always have the mercury solution in *excess* this will do no harm The precipitate or scarlet vermilion, is known chemically as *iodide of mercury*

The iodine, which was chemically bound up with potassium was freed when the iodide solution was mixed with the bichloride of mercury solution there being a greater affinity between the iodine and mercury than between iodine and potassium hence the change. So iodide of potassium and bichloride of mercury when brought together in solution form *iodide of mercury* and chloride of potassium

To purify the color so produced all that is necessary is to allow the precipitate to subside pour off the clear portion (this contains the chloride of potassium which is held in solution) pour upon the precipitate some clean water Allow it to subside About four such washings will remove the impurity Then fold a piece of white blotting paper about ten inches square so as to form a quarter of the sheet Open the fold, pour into it the wet precipitate wash out the tumbler pour the washings into the blotting filter and place the blotting filter into another tumbler or into the same one, if more convenient When the precipitate has become well drained it may be allowed to dry or be used in a moist condition by adding a few drops of gum arabic mucilage being well incorporated with a bone or hard rubber paper knife upon a piece of ground glass, or when dry ground with a pestle in a small mortar, and used as desired The above description of filtering will apply to *all* the following colors.

Pale lemon yellow is made by pouring two or three ounces of the lead solution into a clean tumbler and adding half an ounce of the iodide of potassium solution Stir the mixture well the pale yellow precipitate being *iodide of lead* Wash the precipitate and filter as for the vermilion

Lemon chrome is made by the following mixture Three ounces of lead solution is poured into a tumbler, and two ounces of the bichromate of potash solution poured into it. Stir with a clean glass strip The beautiful rich yellow precipitate is chromate of lead

The chromic acid of the bichromate of potash has combined with the lead of the lead salt (owing to the greater affinity of these two bodies), so that chromate of lead is formed, and acetate or nitrate of potash is formed as the result of chemical combination. Wash the precipitate and filter as before, *always* using a fresh filter paper for each precipitate Pure white or carbonate of lead is made as follows Pour two ounces of the lead solution into a tumbler add about one ounce of the bicarbonate of soda solution a dense white precipitate of pure *carbonate of lead* is formed (white lead), the precipitate being washed and filtered as before In this case the carbonic acid, from the bicarbonate of soda has attacked the lead from the acetate of lead solution, carbonate of lead being formed and acetate of soda.

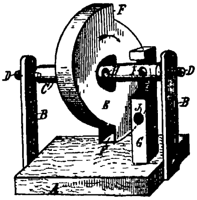
Prussian blue is formed by the following mixture Take three ounces of the red prussiate of potash solution in a clean tumbler pour into this about three ounces of the protosulphate of iron solution, instantly a dense beautiful rich blue precipitate is produced stir this well, the resulting precipitate is Prussian blue In this case the cyanogen that was combined in the red prussiate of potash has seized the iron of the protosulphate and formed *cyanide of iron*, while in the clear solution, when the precipitate subsides is held the sulphate of potash formed by the reaction This precipitate will take some time to subside Never mind this wash this precipitate as before when it will be found that there is one of the finest blue colors produced that it is possible to obtain A beautiful rich brick red is made by pouring into a tumbler four ounces of the nitrate of silver solution, then add thereto three ounces and a half of the bichromate solution, stir this well with a glass strip stir it vigorously because the precipitate is apt to be rather coarse if stirring is not well attended to This precipitate is chromate of silver a very permanent color Although the term brick red is given to it it is more of a purple red a color in fact that cannot be produced by any other means. By preparing the above colors ones self there is not only great pleasure derived but a knowledge that can only be obtained by experiment.

◆

AN INTERESTING PARADOX

BY C H. BOURNE.

In the demonstration of truths of a scientific character, it is sometimes surprising to an experimenter to obtain results seemingly opposed to what we conceive to be a natural sequence of means employed Thinking it may interest some of the readers of the SCIENTIFIC AMERICAN I give the details of a small apparatus which I constructed some time ago As shown in the accompanying engraving the device comprises a baseboard *A* from which rise two supports *B B* A hollow shaft *C* is supported at each end by means of screws *D*, threaded through the vertical supports Mounted on the shaft *C* is a hollow drum *E*, consisting of two semi-cylindrical portions eccentrically connected to form the offsets *F* at opposite sides of the drum These offset portions are open, and provide communication with the interior of the drum Close to one of the supports *B* is a box or air chamber *G*, through which the shaft *C* runs The shaft *C* is provided with an aperture *H* communicating with the interior of the drum, and an aperture *I*, communicating with the interior of the air chamber *G* An opening *J* provides communication with the outside air I have asked a number of persons to predict the result of rapidly rotating the drum in the direction of the arrow (which was done in this case by drawing a cord wound on the shaft), and all have stated their belief to be that the air would be drawn into the drum and would pass through the shaft into the air chamber issuing from the aperture *J* In fact, the result is a current in the opposite direction, as can readily be demonstrated by holding a piece of paper before the opening *J* The paper will be sucked inward. The explanation, of course, is that the centrifugal force of the air in the drum more than balances the exhausting power before the apertures *F F*.



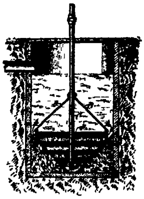
WHICH WAY WILL THE AIR FLOW?

◆

FILTER FOR CISTERNS.

BY CHARLES BRECHT.

The accompanying illustration pictures a method of filtering the water in a cistern so as to make it fit for drinking This filter may be applied to any cistern by simply filling the cistern with stone or concrete in such a manner as to get an inverted conical or pyramidal bottom The device comprises a basket *A*, adapted to fit into this conical bottom The basket is preferably made of sheet iron or steel of light gage, and to prevent it from rusting should be galvanized. The basket should be attached by means of straps *B* to the pump pipe *C* A wire screen *E* fits across the bottom of the basket, and is secured to the pipe *C* just above the perforated bottom section of the pipe This forms a small chamber *D* in which the filtered water collects. Above the screen *E* are placed layers of filtering material, consisting first of coarse gravel over which is laid fine gravel and then a layer of fine sharp sand Above this a layer of charcoal should be placed, then a layer of fine sand a layer of coarse sand a layer of fine gravel, and finally a layer of coarse gravel Over this is placed a coarse wire screen or perforated plate to keep the mass in place



A CISTERN FILTER.

The idea of this arrangement is to do away with any contamination of the water by filtering it only as it is used The wide top of the filtering basket provides a large filtering area while the apex allows as small a volume as possible to stand in the filter basket and become brackish in case of a long drought This small amount may be thrown away if it is found unfit for use and fresh filtered water quickly obtained, at the same time keeping as large a reserve above the filter basket as the size of the cistern will permit.

◆

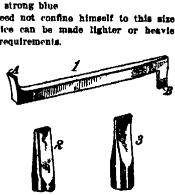
A CLOSE-CORNER SCREW DRIVER.

BY HERBERT R. DAVIS.

The screw driver here illustrated will be a welcome addition to anyone's kit of tools, as sometimes in a close space one cannot turn a regular screw driver with any degree of satisfaction whereas with this screw driver by using first one end and then the other the screw can be tightened up nicely

In use it somewhat resembles an angle wrench Take a piece of ¼ inch square tool steel, about 4½ inches long and heating it to a fair heat bend one end over and form a lip as shown at *A*, Fig 1 Then, turning it one-quarter way round (this is done so that the other end clears the work when using) bend the other end and shape it as at *B* Dress up the blades with a file making them slightly hollow back of the edge of the lip which should be a good 1/64 or 1/32 inch thick Then harden it at as low a heat as possible, and temper to a strong blue

One need not confine himself to this size of steel. The device can be made lighter or heavier to suit various requirements.



CLOSE-CORNER SCREW DRIVER.

Right here a word on the shape of a screw-driver blade may not be amiss. Most of the screw drivers the writer has seen have lips of wedge shape as shown in Fig. 2 When made like this they have a tendency, when in use, to climb out of the slot and damage it so that it is difficult to tighten or loosen the screw.

The blade should be made as in Fig. 3, slightly hollow back of the lip. When made this way it will catch in the bottom of the slot and will not ride out.

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

FORM-GAGE.—Harry R. Burrows, Chicago, Ill. In this patent the invention has for its purpose the provision of a gage suitable to obtain the shape and measure of different sized and proportioned women, for the construction of bust forms and stands upon which to drape their clothing.

ATTACHMENT FOR WEARING-APPAREL.—A. Goldberg, New York, N. Y. By means of this attachment the waist dimensions of garments can be altered to adapt them for use by persons having different waist measurements. It obviates the use of a draw string; requires no alteration in the garment to permit its use in connection therewith, and is inexpensive to manufacture.

GARMENT RACK.—B. Harskowitch, New York, N. Y. This rack supports a plurality of garments. Two members are employed, one of which is normally fixed and the other which is normally movable, and these members are so connected together that the movable member may be pulled out longitudinally together with the garments supported thereby and may then be rotated to better display the garments.

HAT-GUARD.—C. H. Shaw, New York, N. Y. This invention is an improvement in hat guards, and the inventor has in view such a device in which the guard string will be automatically drawn within the hat when released and the effective length of the string altered to suit the convenience of the wearer.

Electrical Devices.

ELECTRIC DETONATOR.—G. A. Allen, Western Springs, Ill. More particularly the invention relates to detonators of the type operated by aid of electricity, the more particular purpose being to guard the explosive materials and exclude the entrance of moisture, so as to preserve in good condition the priming and other explosive substances contained within the detonator shell.

Of Interest to Farmers.

INCUBATOR.—E. A. Maisch, Anderson, Cal. In this electrically heated incubator the invention relates more particularly to the construction of the heating coils and the egg supporting trays. Means provide for an even temperature at all parts of both trays; only a small quantity of current is consumed and the contrivance requires only a simple method of regulation.

BEET DIGGER AND TOPPER.—W. C. Mauer, Greeley, Colo. This improvement is in beet diggers and toppers, and the device is especially adapted for digging and topping sugar beets, which are generally planted in elevated ridges and at spaced distances apart. Beets below a certain size are culled or rejected and the remainder must be topped at the crown.

Of General Interest.

EXERCISING APPARATUS.—W. P. Stull, McKeesport, Pa. In using the apparatus it is clasped in the hand with the thumb on one grip and the fingers on the other, and the hand is opened and closed with the arms pendent, extended and bent to the shoulder or with any other movement of the arms, advisable or desirable. At the same time the body may be bent into various positions.

ADVERTISING DEVICE.—J. E. Dowsing, New York, N. Y. In this instance the invention has reference to advertising devices admitting of general use and more particularly to a type of advertising device suitable for campaign purposes with a view of attracting the attention of the public to a particular candidate.

DOOR HANGER.—F. J. S. Mielt, Gunnison, Colo. This invention relates to door hangers and especially to such as are employed for hanging sliding doors such as car doors, barn doors and the like. The object is to provide a track of improved form which will be reliable in operation, and further, to provide improved means for supporting the track.

Hardware.

STRAINER.—T. Richardson, New Orleans, La. This device is for application to faucets for straining water and other liquids and thereby removing wigglers, bugs and other solid particles. The object of the invention is to provide in such a device a detachable straining element, which is easily applied and displaced for cleansing and other purposes without removing the device from the faucet.

NUT-LOCK.—T. Hand, Walla Walla, Wash. This form of nut lock is much stronger, more rapidly applied and removed and may be manufactured at much less cost on account of its simplicity; there are no key holes or cavities to become clogged; it automatically adjusts itself to a constantly tightening position and may be removed by simply exerting a holding strain on a lug by a crow-bar, pick, or other tool, if the wrench should not be available.

MITER-BOX.—W. E. Sayers, Ellenburg Center, N. Y. This inventor provides a box wherein the saw is guided to operate at a variety of angles from the perpendicular, while operating at various angles on horizontal planes. The operative positions may be readily and quickly adjusted, and means provide for regulating the depth or extent of cutting of the blade.

Heating and Lighting.

BOILER-TUBE CLEANER.—J. D. Thompson, Eureka, Cal. The object here is to provide a cleaner for tubes, which is adapted for directing a jet of steam through the boiler tubes from their rear, it being possible to use the cleaner without dismantling the boiler or furnace in any manner and without drawing the fire from the furnace.

ELECTRICALLY OPERATED WATER HEATER.—J. A. Hunnewell, Lowell, Mass. The more particular purpose of the inventor is to provide a type of heater containing a minimum of parts, the latter being so arranged that water passes through a long tube containing a heating coil, the cold water entering at one end of this tube and the hot water being drawn from the opposite end of the same.

VACUUM AIR VALVE.—C. A. Dunham, Marshalltown, Iowa. This invention pertains to certain improvements in vacuum air valves intended for use in connection with vacuo vapor heating systems, or for any class of heating work in which it is desired to vent air from the mains, returns, or other portion of the system in which low pressure steam is used.

Household Utilities.

WINDOW SHADE SUPPORT.—C. C. Brown, Revelstoke, British Columbia, Canada. The object of this invention is to provide a new and improved window shade support arranged for convenient up and down adjustment on the window to allow moving the shade roller to any desired height and to permit convenient manipulation of the window shade.

FLUSH TANK.—B. Walker, Jr., Austin, Texas. The improvement refers to flush tanks, and the aim is to produce a tank having a valve of simple construction which will operate to close automatically after the water of the tank has run off. A further object is to provide an improved construction for controlling the main lever of the tank which operates the flush valve.

FOLDING CRIB OR BED.—E. Gundelach, New Rochelle, N. Y. The intention in this case is to provide a crib or bed which is simple and durable in construction, exceedingly strong and cheap to manufacture and arranged to permit of conveniently folding it into a comparatively small bundle for transportation or storing purposes.

JAR OPENER.—J. H. Smith, Rochester, N. Y. The object of the invention is to provide an opener for jars containing fruit, vegetables and other food stuffs, and arranged for convenient application to pry the closure open, with a view to break the vacuum in the jar and the adhesiveness of the closure to the jar, thus permitting convenient removal of the closure.

Machines and Mechanical Devices.

REINFORCEMENT FOR BOOK LEAVES.—F. H. Carmi, Los Angeles, Cal. The main purpose here is to strengthen the binding edges of loose sheets to such an extent that the sheets may be moved upon the posts or other binding mechanism without mutilation. Another purpose is to provide a binding edge which will be of the same thickness after reinforcement has been applied, as the main body of the sheet.

SPEEDOMETER.—E. Schneider, XV Staglgasse 8, Vienna, Austria. The speedometer according to this invention is connected to an ordinary clock work which couples a spindle to an indicator device intermittently for a definite period of time so that the index of the indicator is set in accordance with the speed of the spindle at the time.

COIN-SORTER.—T. F. Galligan, Providence, R. I. This apparatus is for use in automatically separating coins according to their several denominations. It has coin delivery openings successively decreasing in size from the top to the bottom passage, according to the size of the coins, a coin carrier in each passage, means for sweeping the coins into the pockets of each carrier and means for revolving the carriers to finally carry those coins remaining in the pockets over the several denomination outlets whereby the coins drop through by gravity.

SAUSAGE TWISTING AND LINKING MACHINE.—W. J. Collins, New York, N. Y. An object in this case is to provide a simple and efficient machine which can be driven from any suitable source of power and which forms sausage links of uniform length. The links may be also formed of different lengths without danger of tearing or injuring the same, and the machine twists the casing so tightly that it cannot subsequently untwist.

TRIGGER MECHANISM.—E. R. Williams, St. Joseph, Mo. The purpose of the inventor is to provide a mechanism provided with a very sensitive auxiliary trigger on the usual or main trigger to securely lock the main trigger and hammer in firing position, and to permit an easy and quick release of the hammer for firing purposes.

Prime Movers and Their Accessories.

COMBINED TIMER AND DISTRIBUTER.—G. T. Brown, New York, N. Y. This invention is for use in connection with multi-cylinder internal combustion engines for controlling the passage of the spark at the igniter. The casing is supported rigidly so that there can be no movement whatsoever, and upon the central shaft the inventor provides a helical contact member movable longitudinally of the shaft and rotatable therewith. The pitch of the helix and position of the helical member on the shaft determine the time of closing of the electric current.

STARTING CRANK FOR INTERNAL-COMBUSTION ENGINES.—J. A. Lawson, New York, N. Y. This invention pertains to improvements in cranks for internal combustion engines and more particularly to an improved means whereby the crank may be locked to the shaft by the mere act of grasping the handle of the crank, and whereby the releasing of the handle will release the grip of the crank upon the shaft.

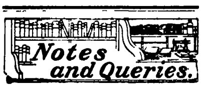
COMBINED TURBINE MUFFLER AND FLY WHEEL.—J. A. Lawson, New York, N. Y. Mr. Lawson not only utilizes the pressure of the gas but he prevents the high temperature of the gas from injuring the wheel rotated thereby. This wheel is so constructed as to operate as a fly wheel, and furthermore he utilizes the wheel in creating a partial vacuum at the exhaust valve or valves of the engine during the cranking or starting of the engine.

Pertaining to Vehicles.

HANDLE BAR FOR BICYCLES.—J. R. Logan, Fresno, Cal. The invention in this case is to provide a bar for bicycles which serves as a receptacle in which the hose employed in connection with a pump for inflating the tires may be stored. By stowing the hose it is always at hand ready for use, and by utilizing the bar a receptacle is provided which is not in the way and adds but little cost to the handle bar.

WEAR STRIP FOR CART AND WAGON BODIES.—J. T. Hamilton, Council Bluffs, Ia. The invention relates to vehicles used for carrying grain and similar material which may leak out at the rear of the vehicle body. The invention strengthens the parts at this point, renders them more durable and operates positively as a preventive of the waste of grain by leakage.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.



Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions, books, etc. This will facilitate answering your questions. *Be sure and give full name and address on every sheet.*

Full hints to correspondents were printed at the head of this column in the issue of March 15th or will be sent by mail on request.

(12129) F. A. McD. says: There has recently been brought out an electrolytic alternating current rectifier consisting mainly, I understand, of aluminium electrodes immersed in a solution of aluminium chloride. If you have ever published any account of the construction of this apparatus or know of any such description having been published I would be pleased to have you advise where I may find the same. A. You will find the electrolytic rectifier described with plans for its construction in SUPPLEMENT Nos. 1478, 1644, 1671, and in the SCIENTIFIC AMERICAN Vol. 97, No. 8, and Vol. 101, No. 7. We send these papers for ten cents each.

(12130) C. C. says: I have quite a lot of dry batteries. They have gone dead. Is there any way they could be charged or worked over to put some life into them? A. Nothing can be done for dead dry cells to revive them as good as new. Sometimes holes are punched in them and they are put into jars as wet cells, getting some current out of them. Sometimes the top is cut out and fresh solution of sal ammoniac is put in. The strength and life of the renewed cell are not enough to pay for the labor and cost.

(12131) J. R. says: Will you kindly *tell me how much per horse-power is the selling* price of electricity when it is generated and sold to consumers. I ask this question for the purpose of framing a basis for a water power which we are trying to have improved. A. The price of electricity in this city is 10 cents per kilowatt hour, either for power or lighting purposes. The kilowatt is the more usual unit of measurement because it may be more conveniently estimated simply by multiplying the voltage of the current by the amperage, e. g., 10 amperes of 250 volt current gives 2,500 watts or 2½ kilowatts. 746 watts or ¾ of a kilowatt nearly are equivalent to one horse power, or one kilowatt = 1 1/3 horse power. The price varies in different parts of the country, being higher at remote coal burning plants where fuel is expensive and lower at hydro-electric generating stations where power costs nothing. The highest price we know is 22 cents per kilowatt hour and the lowest 5 cents, the New York price above quoted being about the average and a fair price to estimate upon.

(12132) C. R. says: Allowing that a man weighing 300 pounds and 3 ounces weighed 300 pounds by spring balance—3 ounces being lost in centrifugal force at sea level equator—what would he weigh at the North Pole, with 13 miles less of earth under him? I say .05 pounds as there is less matter to attract. What would he weigh at the top of a mountain 5 miles high, equator? Would he weigh less than 300 lb. or over the deepest (5 miles) ocean equator? That is, does the water attract as vigorously as earthy matter? Will the SCIENTIFIC AMERICAN get a sea captain to try a common ball with spring balance at sea level New York and then over the deepest ocean abyss? A. The weight of a person at different places on the earth is calculated by the application of Newton's law of gravity. The weight is directly proportional to the attracting mass and inversely proportional to the squares of the distances between the centers of gravity. The results obtained show that a body will weigh about 1/190 part *more* at the poles than at the equator. (See Young's General Astronomy, Chapter V, The Earth as a Globe. We can send the book for $3, postpaid.) The centrifugal force at the equator is 1/289. Hence a man or other body really weighing 300 pounds would seem to weigh a trifle less than 299 pounds at the equator because of centrifugal force. The loss given by you as 3 ounces is too small. At the poles a man whose real weight is 300 pounds at the equator would weigh 301.5 pounds. The earth's mean diameter may be taken as 7,917.6 miles as given by Young in his latest book. The oblateness of the earth is usually taken as 26 miles. From these figures you will see that the equatorial radius is 3965.1 miles and the polar radius is 3952.1 miles. You may disregard the fraction and use only the whole numbers. At the pole there is a little less matter to attract a body and for this reason it would weigh a little less, but at the same time it is brought nearer the center of the attracting body. It is 3952/3965 as far from the center and hence the attraction $(3965/3952)^2$ times as great and the weight is increased to the same degree. The weight on the top of a mountain 5 miles high at the equator would be $(3965/3970)^2$ times the weight at the sea level. We do not know what change of weight there would be over the deepest ocean. Pendulum experiments to determine this are not easy on a ship, nor is accurate weighing very easy on shipboard, certainly not the accurate weighing of a large weight. Balances for weighing heavy articles are not sensitive enough to determine the weight to a small fraction of a unit. We may say that the water attracts less than the rocks of the earth since it is less dense than the rocks. We must leave you with these explanations to figure out the results, since we do not solve problems for correspondents, as you will see by referring to our Hints to Correspondents.

(12133) H. L. T. says: Some years ago I heard of an instrument used by architects to determine the extent of the sun's shadow for any given condition at any particular season of the year. Could you inform me who manufactures or sells this instrument? I have made inquiries from a number of the prominent supply houses without success. A. We do not know any instrument especially for determining the sun's shadow. This can be drawn by a protractor when the altitude of the sun above the horizon has been determined. To find the altitude of the sun for any day at noon, when the shadows are shortest since the sun is highest, you should have the latitude of the place and the declination of the sun. Subtract the latitude of the place from 90 deg. To the remainder add the declination from March 21st to September 21st. From the remainder subtract the declination from September 21st to March 21st. This gives the angle of altitude of the sun at noon above the southern horizon. With this angle the shadow cast by any object can easily be drawn.

(12134) I. Electric Company says: Can you favor us with receipt or formula for the silvering of lens mirrors such as are used for marine searchlights or projectors? A. You will find in our SUPPLEMENT No. [illegible], price ten cents, full and accurate directions for silvering glass for mirrors. The method is the one now in general use, by precipitating silver upon the glass from a solution. With cleanliness and care good results are not difficult to obtain.

(12135) J. D. asks: Are you aware of any plan being discovered how the pyramids of Egypt were built? A. We believe that authorities upon Egyptian antiquities are agreed as to the probable method of handling the stones of the pyramids and the much larger statues and obelisks which were moved hundreds of miles and set up in place. Man power alone can have done the work, and it does not seem necessary to suppose any unknown modes were used for doing the work. With men enough all can be accounted for. Frescoes exhibit such work going on. Some have thought that earth was filled in to form an inclined plane as the pyramid was raised to the higher portions, and the stones were then slid up this plane, which was removed after the building was completed. In modern times such stones have been moved long distances by man power. The base of the statue of Peter the Great in St. Petersburg was dragged from Finland to its present location by men Its weight is estimated at 2,000 tons. Iron rails were laid upon which cannon balls rolled, and thus the huge block was drawn by men

NEW BOOKS, ETC.

KRIECHTIERE UND LURCHE DEUTSCHLANDS. By Dr Kurt Floericke. Kosmos Gesellschaft der Naturfreunde. Geschäftsstelle Franckh'sche Verlagshandlung in Stuttgart. Price, 50 cents.

In this book Dr Floericke has presented a popular account of the principal reptiles and amphibians of Middle Europe To those who are familiar with the German language and desire to obtain a general knowledge of an interesting class of animals without delving into technical details, the book can be recommended.

THE FIXED LAW OF PATENTS By William Macomber Boston Little, Brown & Co 1909 Large 8vo, pp 1,060 Price $7 50 net

In this work Mr Macomber has presented in digested form the patent statutes, the decisions of the Supreme Court of the United States and the decisions of the nine Circuit Courts of Appeals the three constituting what Mr Macomber calls The Fixed Law of Patents. As a piece of compilation and arrangement the book is indeed admirable, as a reference work for the patent lawyer it will be extremely helpful The principles of patent law although fairly few in number and simple in essence, have in later years become more or less befogged in the effort of non technical judges to administer the patent law fairly In view of that fact any attempt to bring something like order out of a chaos of decisions is certainly commendable Because the book gathers up the appellate law, in the language of decisions it should be of interest to the specialist Unless he has digested the law for himself the specialist will hardly have such a compilation Considered as a whole the work may be regarded as an orderly statement of the courts language in important cases, and therefore absolutely authoritative

INNS AND TAVERNS OF OLD LONDON By Henry C Shelley Boston L. C. Page & Co 1909 364 pp Price, $3

The subject of inns and taverns in London has always been a fascinating one, and the literature concerning them is quite voluminous. The present volume sets forth the historical and literary associations of those haunts together with an account of the most notable coffee houses clubs and pleasure gardens of the British metropolis The English have always had a reputation of being essentially a home loving people still in the seventeenth and eighteenth centuries they seem to have exercised considerable zeal in creating substitutes for that home which they ought to have loved above all else When the Londoner had procured his taverns and inns he set to work evolving a new species of public resort in the coffee house That type of establishment appears to have been responsible for the development of the club as the substitute for the home, and then came the age of the pleasure garden Both of the latter survive the one in the form of a more rigid exclusiveness than the eighteenth century Londoner would have dreamed possible the other is so changed that frequenters of the latter would scarcely recognize the relationship The engravings are taken from old prints, and are of great interest The book is beautifully printed and most attractively bound

IMAGINATION IN BUSINESS By Lorin F Deland New York Harper Brothers, 1909 18mo, 108 pp Price, 50 cents net.

This little book contains a number of shrewd essays which deal with a curious phase of business. It shows the remarkable part which imagination plays in business especially to-day

LIGHT AND HEAVY TIMBER FRAMING MADE EASY By Fred T Hodgson Chicago Fred J Drake & Co 1909 12mo, 395 pp Price $1

The present work is a copious treatise on the modern practical methods of executing all kinds of timber framing from the simple scantling shed or lean to to the heavy and complicated timber bridges centers, needling, and shoring roughing and railway work, tank frames and taper structures and is illustrated by 450 engravings and diagrams.

THE ROMANCE OF MODERN MANUFACTURE. By Charles R Gibson Philadelphia J B Lippincott & Co, 1910 12mo, 320 pp. Price $1 50

In the present volume the author has endeavored to trace the evolution of the different industries and to describe in everyday language the methods of modern manufacture in all of the principal industries. It deals with textile machinery laundry machinery, needle machinery thread machinery shoe machinery manufacture of pottery by machinery paper making manufacture of books, artificial light manufacture of confectionery the mechanical baker clocks and watches manufacture of iron making steel rails the railroad and the locomotive building a ship, and other chapters The illustrations and diagrams are particularly clear and we are glad to note a number of the best ones have appeared first in the SCIENTIFIC AMERICAN and that they are reprinted properly credited.

MACHINE DRAWING AND DESIGN FOR BEGINNERS By Henry J Spooner, C.E. New York and London Longmans, Green & Co., 1908. 8vo., 266 pp., 742 illustrations. Price, $1.35

The author is director and professor of mechanical and civil engineering in the Polytechnic School of Engineering in London, and is the author of valuable works on drawing and machine design The work is an excellent one and the drawings which are reproduced are thoroughly common sense. Of course, English practice is slightly different from American but the differences are not so great as to militate against the value of this book. The questions suitable for examination and home work are valuable, but the Board of Education examination papers are worthless for American students.

AN EXPERIMENTAL STUDY OF BAGASSE AND BAGASSE FURNACES By E. W Kerr, M.E., assisted by E. M. Percy B S Baton Rouge, 1909 8vo, 106 pp

During the last few years the writer, who has charge of the instruction of students in the engineering branches of the Audubon Sugar School, has visited a large number of sugar factories in Louisiana for the purpose of gathering data and information for class room use In these visits he has been particularly struck with the lack of uniformity in the methods employed for utilising bagasse as a fuel, both as to the form and proportions as well as to the manipulation of the furnaces. With a view to standardizing as far as possible the methods employed. It was decided to conduct a series of investigations, the object of which should be to gain a thorough insight by general observation and by tests into the methods used in Louisiana for utilising the heat from bagasse The result of the labors of the author is included in the present pamphlet which gives his views on the subject most exhaustively and reflects great credit upon the author

LABORATORY NOTES ON IRON AND STEEL ANALYSES By Walter Macfarlane London and New York Longmans, Green & Co, 1909 12mo. 462 pp Price, $2 50 net.

These notes were in the first instance written for the guidance of the staff in an iron and steel works laboratory which was for some years under the supervision of the author and where the results of over 40 000 estimations were annually placed on record. The methods required to be reliable and rapid. so as to control and keep pace with the manufacturing operations. It was necessary that all the analysts should work on identical lines, and the accuracy of the methods were tested in daily practice and confirmed by other analysts. These notes have been explained and published and are for the benefit of all students. The general aim of the book has been to set out a full course of assaying or analysis in full detail The work is an excellent one and is certain of a considerable sale

MODERN PRACTICE IN MINING Volume II The Sinking of Shafts. By R A. S. Redmayne New York and London Longmans, Green & Co, 1909 8vo, 275 pp Price $2 25 net.

The sinking of shafts for the purpose of opening out and developing mineral wealth constitutes one of the most important branches of mining and although a vast amount of information respecting such operations is disseminated throughout the proceedings of the various mining institutions and excellent chapters are devoted to the subject in many text books on mining so far as the present writer knows shaft sinking has not hitherto been treated from the British standpoint of the work. While the practice described is British practice it cannot help but be of interest to the mining engineers in this country The illustrations are numerous and are well executed on a good scale

AREIKA By D Randall Maciver and C Leonard Woolley With a chapter on Meroitic Inscriptions by F Ll Griffith Oxford The University Press, 1909 4to, 56 pp, 42 plates.

This volume is the first of a series which will record the results of explorations in Egypt planned and financed by Mr Eckley B Coxe Jr of Philadelphia, and this is the first volume of the series to be known as the Eckley B Coxe, Jr, Expedition to Nubia. The expedition is to be conducted for five years on behalf of the University of Pennsylvania and the antiquities that may be obtained will be presented to the University Museum. The district selected for the researches is a part of the country which lies between the First and Second Cataracts, and this first volume records the results obtained in the year 1907 The plates are beautifully executed, and the monograph is an important contribution to the archæology of a section of the world concerning which very little is known.

THE AUTOBIOGRAPHY OF SIR HENRY MORTON STANLEY, K.C.B. By his Wife Dorothy Stanley Cambridge, Mass., and New York Houghton, Mifflin & Co., 1909 8vo 550 pp Price $5 net.

Stanley was a remarkable man, and this revelation of his personal life and of his keen and unprejudiced view of men and affairs stands as one of the books of paramount importance in this field. Of all the interesting and important autobiographies that have seen the light in the last decade none perhaps has a wider appeal to all classes of readers than the autobiography of Henry Morton Stanley. The grim workhouse, the squalid life in Liverpool, the terrible experiences at sea, his adoption by a New Orleans merchant, his life as a planter, the enlistment in the Confederate army, the wonderful picture of Shiloh, his life in prison and escape, his finding of Livingstone, the exploration of the Dark Continent, the founding of the Congo State and his closing years are described with a vigor of style which has rarely been surpassed. The book is beautifully printed and illustrated, and is certain to have a large sale, as it appeals to almost everyone

MECHANICAL DRAWING FOR TRADE SCHOOLS. By Charles C Leeds. New York D. Van Nostrand Company, 1909 Oblong 4to, 58 plates and text. Price, $2

This work on mechanical drawing has been prepared with a purpose in view of thoroughly grounding draftsmen and others of the various machinery trades in the principles of mechanical drawing It is also intended to familiarise them with modern drafting room practice The author does not believe in using models, as he thinks this tends to develop copyists, and in this he is undoubtedly correct. The author who is connected with the Carnegie Technical Schools, finds that the results obtained by this system are excellent. The plates are on an enlarged scale and the drawings from which they are made are well executed There is a bill of material with nearly every plate.

IRRIGATION ENGINEERING. By Herbert M. Wilson, C.E. New York John Wiley & Sons, 1909 8vo, 625 pp Price, $4 net.

The Reclamation Service of the United States now has 21 projects which have reached such a state of completion that water is being furnished settlers for irrigation of their lands. At this date 675,514 acres are under irrigation from Reclamation projects and $42,932,787 have been expended upon the construction of works completed or in progress The revenues collected to date from projects in operation and available under the law for re-expenditure on future construction amount to $1 070 506 The present or sixth edition has been almost entirely rewritten bringing up to date the tremendous progress made in construction by the Reclamation Service Since the last edition important changes have been produced in the design and in the materials used in structures on irrigation works as a result of the very general adoption of reinforced concrete for such works.

ARCHITECTURAL PERSPECTIVE. By I P Hicks New York Industrial Publication Company, 1909 Square 12mo, 38 pp Price, 50 cents.

BUILDING PLANS AND HOW TO DRAW THEM By I P Hicks. New York Industrial Publication Company 1909 Square 8vo, 73 pp Price, 50 cents.

60 YEARS' EXPERIENCE

PATENTS

TRADE MARKS
DESIGNS
COPYRIGHTS &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO, 361 Broadway, New York
Branch Office, 625 F St., Washington, D. C.

INDEX OF INVENTIONS

For which Letters Patent of the
United States were Issued
for the Week Ending
November 2, 1909,
AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Acid, new mercury salt of para-aminophenylarsinic, J. Altschul . . . . [illegible]
Adding machine, F. R. McBerty . . . . [illegible]
Adding machine actuating mechanism, G. F. Wetmore . . . . [illegible]
[illegible]
[illegible]
[illegible]
Antifriction compound, [illegible] . . . . [illegible]
Arch centering form, collapsible, A. E. Smith . . . . [illegible]
Asphalt, rejuvenating, J. A. Dow . . . . [illegible]
Assaying composition, J. C. Hamer . . . . [illegible]
Atomizer, T. A. De Vilbiss . . . . [illegible]
Auger, coal, C. R. Anderson . . . . [illegible]
Automobile driving gear, H. C. Whitehurst . . . . [illegible]
Automobile touring lamp carrier, M. Dudley . . . . [illegible]
Axle and making same, steel car, A. C. Cunningham . . . . [illegible]
Axle lubricator, car, Hardy & Bell . . . . [illegible]
Baby clothes, receptacle for, C. Brown . . . . [illegible]
Balloon, dirigible, R. D. Reese . . . . [illegible]
Band cutter, J. H. Deane . . . . [illegible]
Barrel head and hoop fastener, E. Dixon . . . . [illegible]
Basket, C. H. Mosley . . . . [illegible]
Baskets, boxes, etc., corner iron for, F. W Goodale . . . . [illegible]
Battery contact, J H Gugler . . . . [illegible]
Bearing, antifriction, L. Moss . . . . [illegible]
Bearing, roller O. M. Michaud . . . . [illegible], [illegible]
Bed, folding wall, W. C. James . . . . [illegible]
Bed spring, Birr & Kleine . . . . [illegible]
Beer, bottling, R. Gull . . . . [illegible]
Beer bottling machine, R. Gull . . . . [illegible]
Belt coupling, C. E. Purple, et al . . . . [illegible]
Belt coupling, C. E. Purple . . . . [illegible]
Belt sander, O. Olsson . . . . [illegible]
Belt shifting mechanism, A. A. Wood . . . . [illegible]
Belt, sorting, D. Hutter . . . . [illegible]
Bench clamp, M. T. Bond . . . . [illegible]
Bench stop, M. R. Raynesford . . . . [illegible]
Bending machine, E. A. Carter . . . . [illegible]
Berth, sleeping car A. West . . . . [illegible]
Bevel, jack rafter, C F Braun . . . . [illegible]
Binder, H. V Wagoner . . . . [illegible]
Binder, loose leaf E. P Webster . . . . [illegible]
Binding post, H. E. Leppert . . . . [illegible]
Block. See Building block.
Blower, air flue, L. Lanstrum . . . . [illegible]
Book, check, C. S. Saltzer . . . . [illegible]
Book, folding check, C S. Saltzer . . . . [illegible]
Book, manifolding, B. C. Maxwell . . . . [illegible]
Book or pad, manifolding, B. C. Maxwell, 939,150, [illegible]
Book, pocket check C S. Saltzer . . . . [illegible]
Bottle capping machine, R. L. Shriner . . . . [illegible]
Bottle capping machine, G Kirkegaard . . . . [illegible]
Bottle closure, F W H. Clay . . . . [illegible]
Bottle closure, Coffman & Best . . . . [illegible]
Bottle, non-refillable M. Raymond . . . . [illegible]
Bottle, non-refillable, R. Riegel . . . . [illegible]
Bottle, siphon, P. Devarco . . . . [illegible]
Bowl, sugar C. T McCreery . . . . [illegible]
Box, M. M King . . . . [illegible]
Box, J H Baker . . . . [illegible]
Box, G B. Reed . . . . [illegible]
Brake beam C. H. Williams, Jr . . . . [illegible]
Brake head, adjustable, W A. Holzschuh . . . . [illegible]
Brake mast, H C. Ostermann . . . . [illegible]
Brake slack adjuster, automatic, E. F Hamilton . . . . [illegible]
Brick press, S. J Fink . . . . [illegible]
Bristle drying machine, [illegible] Zeiner . . . . [illegible]
Broom head cover O T [illegible] . . . . [illegible]
Brush, Wolfgram & Klaumann . . . . [illegible]
Brush, Ahlstedt & Bowman . . . . [illegible]
Buckle and clasp, combined, M F Burns . . . . [illegible]
Buckle cross line W D Wise . . . . [illegible]
Building blocks, musical, A. A. Gilbin . . . . [illegible]
Building structure V Font . . . . [illegible]
Burner, H. W Schoff . . . . [illegible]
Bust pad, A. O Henderson . . . . [illegible]
Butter and lard cutter, C H. Carlson . . . . [illegible]
Butter apparatus for the continuous manufacture of A H Borgstrom 938,815
Buttonhole attachment, substitute F Robertson . . . . [illegible]
Cable traction apparatus C J Eastman . . . . [illegible]
Cables, clamping mechanism for litter supporting, W Ostenkunst . . . . [illegible]
Calculating machine J Bricken . . . . [illegible]
Calculating machine, R Rein 938,790, [illegible]
Can caps, machine for applying cement to, W F Butler . . . . [illegible]
Can cover coating machine, G W F Weber et al . . . . [illegible]
Can cutter and tapping valve, oil, W M Curtis . . . . [illegible]
Can drier, labeled, R. Schilling . . . . [illegible]
Can neck and making the same, milk R. Bray . . . . [illegible]
Candlestick, miner's, C. Fisk . . . . [illegible]
Car brake, N P Zech . . . . [illegible]
Car door and means for operating it W M. Smith . . . . [illegible]
Car door for grain, coal, etc., R. R. Reavley . . . . [illegible]
Car, dump, C. H Clark . . . . [illegible]
Car fender G A. Bisler . . . . [illegible]
Car grain door lock, box C O French . . . . [illegible]
Car railway motor Hovey & Bix . . . . [illegible]
Car track sanding device W R. Fielding . . . . [illegible]
Car underframe bolster construction, F Koch . . . . [illegible]
Car wheel and mounting T Donohoe . . . . [illegible]
Carbid and manufacturing same H. L Hartenstein . . . . [illegible]
Carbureter S W Rapp . . . . [illegible]
Carriage top, W Woop . . . . [illegible]
Carton G W Teasdale . . . . [illegible]
Cash register, R. J von Pein . . . . [illegible]
Caster B. H. Humphrey . . . . [illegible]
Caster, B. H. Noelting . . . . [illegible]
Caster furniture, B H. Humphrey . . . . [illegible]
Casting metals, W. G Nichols [illegible], [illegible]
Casting plant C. W Sherman . . . . [illegible]
Catamenial bandage C. B Cahoon . . . . [illegible]
Cement and other products, making, S. Peacock . . . . [illegible]
Cement sidewalks or similar structures, apparatus and process for laying, A. D. Nay . . . . [illegible]
Chair See Folding chair
Chair, M Thum . . . . [illegible]
Chair attachment, barber, T G. Aitkin . . . . [illegible]
Chair seat, A. Wamper, Jr . . . . [illegible]
Chalk holder Norman & Peterson . . . . [illegible]
Channel bars with taperless flanges, making H. Sack . . . . [illegible]
Chuck, automatic H O Evans . . . . [illegible]
Chuck, drill, B N Kennedy . . . . [illegible]
Chuck, drill, C F Schultz . . . . [illegible]
Chuck lathe, and drilling, W Kleber . . . . [illegible]
Clamping device J W Higgins . . . . [illegible]
Clevis hook, whiffletree, W S. Thomson . . . . [illegible]
Clothes line hanger C C. Lovejoy . . . . [illegible]
Clothes line reel and tightener, R. M. Knowley . . . . [illegible]
Clothes line tightener, Schauer & Marek . . . . [illegible]
Clothes press, steam, A. J Hoffman . . . . [illegible]
Cluster, wireless, H. S. Benjamin . . . . [illegible]
Clutch actuating mechanism, B. M. W Hanson . . . . [illegible]
Clutches, duplex thrust device for friction, A. Lambert . . . . [illegible]
Coal loading apparatus, W Larson . . . . [illegible]
Cock, ball W J Frost . . . . [illegible]
Coffee machine, C. Nelson . . . . [illegible]
Coin holder, A. E. Volva . . . . [illegible]
Coke oven, by-product retort, H Dranties . . . . [illegible]
Coloring matter vat, L. Dufert, [illegible], [illegible]
Comfortables, sanitary washable case for, A. C. Caldwell . . . . [illegible]
Communication selective in systems of, E. E. Clement [illegible], [illegible]
Communication, selective apparatus for systems of, E. E. Clement . . . . [illegible]
Computing machine check stamping mechanism, G A. Armstrong . . . . [illegible]
Computing table, E. Aberle . . . . [illegible]
Concrete construction, C. E. [illegible] . . . . [illegible]
Concrete molding machine, combination, [illegible] H. Wiest . . . . [illegible]

FRICTION DISK DRILL

FOR LIGHT WORK.
Has These Great Advantages:

The speed can be instantly changed from 0 to 1600 without stopping or shifting belts. Power applied can be graduated to drive, with equal safety, the smallest or largest drills within its range—a wonderful economy in time and great saving in drill breakage. ☞ Send for Drill Catalogue.

How to Construct An Independent Interrupter

In SCIENTIFIC AMERICAN SUPPLEMENT 1615, A. Frederick Collins describes fully and clearly with the help of good drawings how an independent multiple interrupter may be constructed for a large induction coil.

This article should be read in connection with Mr Collins' article in SCIENTIFIC AMERICAN SUPPLEMENT, 1605, "How to Construct a 100-Mile Wireless Telegraph Outfit."

Each Supplement costs 10 cents; 20 cents for the two. Order from your newsdealer or from

Two Good Books for Steel Workers

Hardening, Tempering, Annealing and Forging of Steel

By JOSEPH V. WOODWORTH

Size 6½ x 9½ inches. 288 pages. 201 illustrations. Price $2.50 postpaid

THIS is a practical work, treating clearly and concisely modern processes for the heating, annealing, forging, welding, hardening and tempering of steel, making it a book of great value to toolmakers and metal-working mechanics in general. Special directions are given for the successful hardening and tempering of steel tools of all descriptions, including milling cutters, taps, thread dies, reamers, hollow mills, punches and dies and various metal-working tools, shear blades, saws, fine cutlery and other implements of steel, both large and small. The uses to which the leading brands of steel may be adapted are discussed, and their treatment for working under different conditions explained; also special methods for the hardening and tempering of special brands. A chapter on case-hardening is also included.

The American Steel Worker

By E. R. MARKHAM

Size 5½ x 8 inches. 367 pages. 163 illustrations. Price $2.50 postpaid

THIS is a standard work on selecting, annealing, hardening and tempering all grades of steel, by an acknowledged authority. The author has had twenty-five years practical experience in steel-working, during which time he has collected much of the material for this book. Careful instructions are given for every detail of every tool. Among the subjects treated are, the selection of steel to meet various requirements, how to tell steel when you see it; reasons for different steels; how to treat steel in the making of small tools, taps, reamers, drills, milling cutters; hardening and tempering dies; pack-hardening; case-hardening; annealing; heating apparatus, mixtures and baths, the best kind, and why; and in fact everything that a steel-worker would want to know is contained in this book.

OUR SPECIAL OFFER: The price of these books is $2.50 each, but when the two volumes are ordered from us at one time, we send them prepaid to any address in the world on receipt of $4.00.

MAKING ALCOHOL FROM WOOD WASTE.

(*Continued from page 352.*)

gallon of alcohol, and the process costs another 6 cents, the actual cost of production being therefore about 32 cents.

The Standard Alcohol Company, owners of Messrs. Ewen and Tomlinson's patents, produces a gallon of equally pure alcohol from 57 cubic feet of sawdust, hitherto considered valueless, but costing if bought for manufacturing purposes, at the outside 26 cents a ton. The cost of conversion and distillation is about 4 cents a gallon and the total cost of materials, process, barrels, etc., does not exceed 10 cents a gallon.

The comparative cost of producing denatured alcohol is still more in the Standard Company's favor.

Wood and other vegetable fibers as is generally known, contain a large proportion of starchy matter, which can be converted into sugar by treatment with acids. This process goes on constantly in the human body, the stomach being unable to digest starch but using its nutritive constituents when converted by the digestive juices into sugar.

The same change must be brought about in the wood waste before fermentation for the generation of alcohol is possible.

For this purpose the wood waste in the Standard Company's process is introduced into the cylindrical "digester" shown in our illustration, the door closed, and a mixture of steam and sulphurous acid introduced by an internal spray pipe while the machine is revolved. The acid acts on the starch in the wood, and at the same time the heat volatilizes the turpentine and other resinous matter in the woods used. The digester is lined with a special kind of brick to resist acid.

Upon completion of the digestion the steam and gases are exhausted under water, which absorbs the surplus acid and liquefies the turpentine.

The treated material is then removed from the digester, and carried by conveyers to the diffusion batteries, upon the screens of which it is deposited. There it is washed by clean water, which passes through all the cells in series becoming a stronger and stronger sugar solution. The cells are so arranged that each is filled in turn and each in turn, when it has been washed longest, receives the fresh water, after which it is emptied of the washed residues. The liquor is next neutralized with lime, any acidity preventing fermentation, pumped into a tank and allowed to settle, the clear liquid being then pumped to the distillery fermenting tanks. A special yeast, similar to brewers' yeast, is added, and fermentation begins from this point, the process being no different to that of making grain alcohol.

Every kind and form of wood has been used, but always with the same results, a purer alcohol being obtained than that which is generally obtained from grain. Every stage of the process has been carried on under supervision of U. S. government inspectors, and the usual licenses have been taken out.

Tests have been performed by other companies with their own staff in the Standard Company's plant, excluding everyone who has been connected with former experiments, entirely confirming the Standard Company's results and resulting in contracts for the use of the plant under license.

The utility of this process to lumbermen will immediately be appreciated. The refuse burned will be eliminated, and if a hundred tons of wood waste a day is produced at a mill, 1,200 to 1,500 gallons of alcohol may be made from it, supplying a large quantity of power for other purposes, and still leaving the refuse with its fuel value but little diminished. The resins are extracted from pine and similar woods in the process, but the residue discharged from the diffusion battery in the alcohol process may be made into briquettes or charcoal, forming a desirable fuel salable at a good profit. Smaller mills making less than 50 tons of waste

A Prodigy in Power Is This Engine!

A Portable Power Plant, Complete in Itself

Here's a new type of gasoline engine that has scored a tremendous success. A prodigy in power. Note how it differs in looks from ordinary gasoline engines.

This is the key to its greatness. It's a complete, portable **Power Plant**! Needs no cement foundation—no anchor posts—no belts—no arms. Always ready any time, anywhere!

The Fuller & Johnson
FARM
PUMP ENGINE

For Farms and Country Homes

This engine is just what you need for farm or country homes. Clamps to any pump standard. Works in any well. Pumps 500 to 1000 gallons per hour. Cannot Freeze in Coldest Weather. Cannot overheat. Has pulley for running light machinery. Can be detached and taken anywhere easily. Affords **FIRE PROTECTION**. Same high grade as best automobile engines. Equal in quality to high-powered Fuller & Johnson Engines known the world over. Simplest, neatest strongest handiest, most adaptable little engine on the market. Costs less than a good windmill. Write for catalog, price and name of nearest agent.

Dealers! Write for AGENCY

Fuller & Johnson Mfg. Co. 465 Henry St., Madison, Wis.
Established 1840.

MEN WANTED

1200 men average $6.92 profit per day

Selling "WEAR EVER" Aluminum Specialties

Half of these men had no previous experience. Work made pleasant by our 1 6 page instruction Book. No drudgery or canvassing. Let us show you what others have done. Address

The Aluminum Cooking Utensil Co. Desk 25, Pittsburg, Pa.

Opportunity knocks, but don't expect the door to be kicked in.

Deaf Persons

after trying electrical and other devices find that the

Otophone

is the best thing to aid to hearing. No rubbing, no wires or battery. A small compact instrument held against the ear not inserted. Reproduces natural voice tones very effectively; no buzzing. Manufactured in our surgical instrument department. Our **TRIAL** offer and testimonials will interest you.

Send to-day for illustrated booklet K

E. B. Meyrowitz

Optician
Manufacturer of Surgical Instruments and Electrical Appliances
104 East 23d Street, New York

A FLOOD OF LIGHT FROM KEROSENE (Coal Oil)

Burning common kerosene the **ALADDIN MANTLE LAMP** generates gas that gives a light more brilliant than city gas, gasoline or electricity. Simple, odorless, clean, safe and durable; is revolutionizing lighting everywhere.

Biggest Money Maker for Agents

Needed in every home. Every lamp guaranteed. Sells itself. Ask our nearest office how you can get a lamp free or apply for agency proposition. THE MANTLE LAMP CO. of America, Desk 89, Chicago, Portland, Ore., Waterbury Conn. Winnipeg, Can.

Instructive Scientific Papers

ON TIMELY TOPICS

Price 10 Cents each by mail

ARTIFICIAL STONE. By L. P. Ford. A paper of immense practical value to the architect and builder. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

THE SHRINKAGE AND WARPING OF TIMBER. By Harold Busbridge. An excellent presentation of modern views, fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER. By N. Monroe Hopkins. Fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

DIRECT VISION SPECTROSCOPES. By T. H. Blakesley, M.A. An admirably written instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No. 1493.

HOME MADE DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 161 and 600 contain excellent articles with full drawings.

PLATING DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them.

DYNAMO AND MOTOR COMBINED. Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 844 and 865. The machines can be run either as dynamos or motors.

ELECTRICAL MOTORS. Their Construction at Home. SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641.

Price 10 Cents each, by mail

Order through your newsdealer or from
MUNN & COMPANY, Inc.

(*Concluded from page 359.*)

a day may profitably combine to operate a joint distillery for the conversion of their refuse into alcohol.

Whereas it may be not a little alarming to the prohibitionists to suggest that a drinkable alcohol may be so cheaply made from sawdust, much as one may deprecate the manufacture of artificial wines and liquors and adulteration with alcohol, it is at least satisfactory that the product of the new process is actually purer than that made from grain.

◆

TRIALS OF THE "NORTH DAKOTA."

(*Continued from page 352.*)

that of the motors being identical.

The five trials of the "North Dakota" over the mile course gave the following speeds 22.25, 21.48, 22.13, 21.51, and 23.13, the average speed working out at 21.83 knots. She thus not only exceeded the mean speed of the "Delaware" by 0.39 knot, but the turbines exceeded the reciprocating engines by over 5000 horse-power. The maximum number of revolutions of her propellers was 286 a minute, and it was found that 263 revolutions were sufficient to maintain the contract speed of 21 knots.

In the four-hour test under full power the "North Dakota" made 21.71 knots for the first two hours, and 21.64 knots in the third hour. On the fourth mile the failure of a tube in one of the boilers necessitated the shutting down of four out of the fourteen boilers, but even under this greatly reduced power, the speed of the ship was exactly 21 knots.

A feature which, from the military standpoint, is of the greatest importance is the remarkable steadiness of the ship, even when the turbines are being pushed to the limit. Throughout the greater part of the length of the ship it was scarcely possible to tell, from any vibration, that the engines were in motion. This is a feature which is particularly appreciated by ordnance officers, since the vibration which is noticeable on ships driven by reciprocating engines is more or less disturbing to the gun sights. The "North Dakota," which is considerably the largest warship yet built for our navy, has been constructed in record time, and the Fore River Company is to be congratulated on the fact that, had it not been for delays in the furnishing of armor they would have cut down the record for construction even more than they have. Her dimensions are: Total length, 518 feet 9 inches, beam, 85 feet 2½ inches, draft on trial, 27 feet, displacement on trial, 20,000 tons. She is the most completely armored ship afloat. Her main belt, 7 feet 6 inches wide, tapers from 10 inches at its bottom edge to 12 inches at its top edge. Above this, extending to the gun deck, is a second belt 8 feet wide, tapering from 10 inches at its bottom edge to 8 inches at the top. The 5-inch guns have a protection of 5 inches of armor, and the main turrets and barbettes are protected by 11 inches.

The lines of the ship are particularly fine, in fact, as fine as those of our armored cruisers. She will prove to be a splendid vessel when heading into a heavy sea, for not only has she freeboard, due to her forecastle deck, of 27 feet, but she is given a very pronounced outward flare, which should serve to lift her comfortably over the waves, and enable the ship to be driven at full speed in heavy weather. An innovation is the placing of the officers' quarters forward under the forecastle deck and in the superstructure immediately abaft of the two forward turrets.

The battery is mounted on the longitudinal axis of the ship, a disposition which originated with our Construction Department, and is being followed by some foreign navies. The placing of all the guns on the center line enables the whole battery to be trained on either beam, giving the ship a broadside discharge either to port or starboard of ten 12-inch guns. This arrangement, it is true, weakens the end-on fire, which, in

Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value, of which over 17,000 are listed in a carefully prepared catalogue, which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical, or engineering subject on which special information is desired, some papers will be found in this catalogue, in which it is fully discussed by competent authority.

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS. The article tells how a small and simple experimental installation can be set up at home. Scientific American Supplement 1551.

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME, is described in Scientific American Supplement 1566.

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement 1566.

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT is told by A. Frederick Collins in Scientific American Supplement 1605.

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that anyone can make it.

A ¼-H.P. ALTERNATING CURRENT DYNAMO. Scientific American Supplement 1558.

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement 1574.

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX, PINS, AND A RUBBER BAND is the subject of an article in Scientific American Supplement 1578.

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement 1582, with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY. In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid, to explain the meaning of capillary elevation and depression, to serve as a hydraulic tourniquet, an aspirator and intermittent siphon, to demonstrate the ascent of liquids in exhaustive tubes, to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement 1583.

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement 1584.

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER. Clear diagrams giving actual dimensions are published. Scientific American Supplement 1615.

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement 1618. A plunge battery of six cells, a two-inch spark induction coil, a pair of one-pint Leyden jars, and an inductance coil and all the apparatus required, most of which can be made at home.

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements 1363 and 1381.

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained, with the help of diagrams, in Scientific American Supplement 1622.

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT, illustrated with diagrams, Scientific American Supplement 1623.

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE, illustrated with diagrams, Scientific American Supplement 1624.

HOW TO MAKE A MAGIC LANTERN, Scientific American Supplement 1546.

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement 1555.

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement 1561.

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained with the help of illustrations, in Scientific American Supplement 1573.

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement 1594.

Good articles on SMALL WATER MOTORS are contained in Scientific American Supplements 1494, 1049, and 1690.

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement 1472.

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement 1433.

A SEWING-MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement 1210.

A WHEATSTONE BRIDGE, Scientific American Supplement 1595.

Good articles on INDUCTION COILS are contained in Scientific American Supplements 1514, 1522, and 1527. Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement 966.

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement 1527.

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements 1561, 1563, and 1566.

ANEROID BAROMETERS, Scientific American Supplements 1500 and 1554.

A WATER BATH, Scientific American Supplement 1464.

A CHEAP LATHE UPON WHICH MUCH VALUABLE WORK CAN BE DONE forms the subject of an article contained in Scientific American Supplement 1562.

Each number of the Scientific American Supplement costs 10 cents by mail.

BUSINESS OPPORTUNITIES

BUILD A $5,000 BUSINESS in two years. Let us start you in the collection business. No capital needed; big field. We teach secrets of collecting money; refer business to you. Write today for Free Pointers and new plans. Am. Collection Service, 22 State St., Detroit, Mich.

Inquiry No. 8968.—Wanted to buy nickeloid for buttons.

MANUFACTURERS.—Bids wanted for small internally geared friction clutches, from 2 to 8 inches diameter. Answer, Room 1111, Flatiron Building New York City

Inquiry No. 8969.—For the address of the Windsor Mfg. Co., manufacturers of waterproof collars and cuffs.

ANYONE, anywhere, can start a mail order business at home. No canvassing. Be your own boss. Send for free booklet. Tells how. Heacock, [illegible], Lockport, N Y

Inquiry No. 8914.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug"

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres., The Nat'l Co-op. Real Estate Co., Suite [illegible], Marden Bldg., Washington D. C.

Inquiry No. 8967.—Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

EDUCATIONAL.

CIVIL SERVICE EMPLOYEES are paid well for easy work; examinations of all kinds soon; expert advice, sample questions and Booklet 40 describing positions and telling easiest and quickest way to secure them free. Washington Civil Service School, Washington D. C.

Inquiry No. 8996.—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

PATENTS FOR SALE

FOR SALE.—Patent No. [illegible]. Improvements on airships and aeroplanes. For further information write to A. E. G. Lubka, [illegible] Clayton Street, San Francisco, Cal.

Inquiry No. 8999. For information regarding shoes not made of leather but similar to the same and are as durable.

FOR SALE.—Patent for preserving and purifying milk and cream to keep indefinitely in sealed cans, and for Pasteurizing in 5 and 10-gallon tanks for commercial use. For further particulars address Mr A. V Russell, Newman, California.

Inquiry No. 9001.—For the address of progressive manufacturers of fruit jars.

FOR SALE. Patent No. [illegible]. An improved lathe rest for holding cylinders while being bored in an engine lathe. For further particulars address A. R. Whiting, Weston, W Va.

Inquiry No. 9010.—Wanted to buy a "Rector Help-a-Phone."

FOR SALE.—Combined folding ironing table and sleeve board. Is adjustable to any height; folds into a compact bundle; special shirt board feature. Can be manufactured for [illegible] each. Must sell. Send offer or write for particulars. Theo. U. Krings, Clarinda, Iowa.

Inquiry No. 9014.—For manufacturers of machinery, supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

PATENT FOR SALE.—Combination trunk and typewriter desk; a very useful device for travelers. The change can be made in a minute from a trunk to office desk, with typewriter in place, and pigeon hole annex; remove typewriter and put in its place a looking glass, and you will have a perfect dressing table useful for either sex. I will sell this patent outright or grant license to manufacture on royalty. U. S. Patent No. [illegible], April [illegible], 1909. Address M. E. Schultze, Southampton, N Y

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

FOR SALE.

FOR SALE on a royalty basis, a Bundle Tying Machine for mercantile use. A new field of enormous possibilities. Cheap in comparison with its need. Address J W Hall, Wrightstown, Pa.

Inquiry No. 9018. Wanted the address of parties manufacturing gold-plated pens for use in cheap fountain pens.

FOR SALE.—Engine lathe, swings 9½ in., takes 28 in. between centers. Complete with full set change gears to cut all size threads, 8 to 40 in. Price only [illegible]. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9022.—Wanted to buy a light, small motor, not exceeding three pounds in weight, including everything in going order

TYPEWRITERS.

REAL REMINGTON, $18.—One machine only in new localities to secure desirable agent. Special agents prices supplied on all makes of typewriters. Tribbons [illegible]. Standard Typewriter Exchange, 23 Park Row, New York.

Inquiry No. 9023.—Wanted, to buy silk machines from [illegible], twisting, doubling, to the final process of making it into clothes.

MISCELLANEOUS.

"LIBERTY, HEAT, MAGNETISM AND ELECTRICITY are all one and the same thing." If you wish to know why they are, send 25c. cash for a copy of this pamphlet to A. E. [illegible], [illegible] Pa.

Inquiry No. 9045.—Wanted, address of rubber manufacturers in Germany

WANTED.—[illegible]

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9025.—Wanted, address of parties who make "invar" or other metals having a low coefficient of expansion.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9028.—Wanted, to buy a washing machine that is run by a coil spring motor

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw to manufacturing straw hats.

Inquiry No. 9030.—Wanted, the address of firms manufacturing a wood fiber bottle and case made from same material.

Inquiry No. 9034.—For manufacturers of machinery that would reduce stumps to kindling wood.

Inquiry No. 9036. Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

(Concluded from page 360)

these ships, consists of only four guns, as against six guns in several foreign navies, but it is the belief of our naval officers that future engagements will be fought almost entirely broadside to broadside. Personally, we are inclined to the belief that if the third and fourth turrets were staggered, the third being moved over to starboard and the fourth turret to port, the effectiveness of the gunfire would be increased without diminishing the broadside fire.

The foremost pair of guns have a command of 33 feet. The pair immediately astern have a command of 41 feet. Turret No 3 carries its guns about 89 feet above the sea, and those in the two after turrets have a command of about 25 feet. We shall hope in a later article to give further particulars of the trials of this vessel.

◆

Radiations of Short Wave Length

At the recent meeting of the British Association for the Advancement of Science at Winnipeg Prof. Lyman, of Harvard University described his interesting researches on radiations of very short wave lengths. The radiations involved in ordinary laboratory work are comprised between 6,800 and 2,600 of Angstrom's scale. Schumann has demonstrated the great effect of the atmosphere in limiting the spectrum in the ultra violet region. By the employment of lenses of fluorine Prof Lyman has extended Schumann's researches, especially to the region between 2 000 and 1 030 Angstrom which exhibits peculiarities of great interest. No visible hydrogen line was found between 2 000 and 1 650. Between 1 650 and 1 030 conspicuous lines of hydrogen were observed but they did not exhibit the grouping which is characteristic of hydrogen lines in other parts of the spectrum. No lines of nitrogen, oxygen, or helium and only a few lines of argon were detected between 2 000 and 1 030. In this region carbon dioxide and carbon monoxide show spectra of many bands. Hydrogen, argon and helium are very transparent to these radiations, but oxygen absorbs them energetically. Here, probably, is the explanation of the opacity of air to these radiations. Prof Lyman has corrected the limit of absorption by fluorine. This absorption begins at 1 265 Angstrom and not at 846 as had previously been believed. The chemical effects of these radiations of short wave length are very intense. Oxygen especially at low pressures, is strongly ozonized. Gases, in general, are ionized the more strongly as their pressure is lowered. Bumstead has shown that the photochemical action of these radiations is 25 times more intense than that of ordinary ultra violet rays.—La Nature

The Fortieth Birthday of the Post Card.

The first post cards were issued in Austria on October 1st, 1869. The idea had already been suggested, but not adopted, at the fifth German postal congress, in 1865. Its adoption in Austria appears to be due to an article published in 1869 by Prof. Emanuel Hermann of Vienna, who is sometimes called the inventor of the post card. In 1870 post cards were issued by the North German Postal Union, Bavaria, England, and

TRY THE NEVER FAIL 15 DAYS

$1
AND THE COUPON
BRINGS THIS
THREE DOLLAR
NEVER FAIL
STROPPER

Then, if you can't say with perfect truth, "Never have I enjoyed such soothing shaves," send it right back at our expense and we'll return your money.

With the Never Fail, every user is at once an expert. You can instantly sharpen any razor—any style blade—and make it better than the day it passed the shop inspector. Better honed sharper than it can be made by the most expert hand operator, and in much less time. Only a few strokes on either side does the trick—five or six seconds. If you use safety blades, the **NEVER FAIL WILL MAKE EVERY ONE OF THEM GOOD FOR FROM 60 to 150 PERFECT SHAVES** so it will pay for itself in money as well as time saved.

We are so positive the Never Fail will make good, that we issue the exceptional offer contained in the center of this advertisement. We want you to enjoy a Never Fail like thousands of others. We want you to know, by experience, the pleasure of a smooth, soothing, comfortable shave—a shave only possible with a Never Fail Stropper.

Remit only a third of the price—and that simply as an evidence of good faith. Could we choose our inquirers we'd gladly send it free. Send just $1 00. Try the Never Fail 15 days. Subject it to the severest tests. Then, if not completely satisfied—if not the best stropper you ever used—if it doesn't do just as we say, send for your money.

There never was a shaving problem; it has always been a sharpening problem. Any man can use a razor provided his blades are properly sharpened.

We could tell you about the way the Never Fail is made, but you don't care to hear it. You only want to be certain of a GOOD stropper, one that will positively end your shaving troubles. We have it in the Never Fail. One dollar and the coupon will prove it, and your dollar is simply on deposit while you judge.

Don't go on shaving the old way—the torturing way. Don't waste time and money and undergo the risks of the barber shop. Shave every day in your own home at the same time you complete the rest of your morning toilet. Carry the clean, well-groomed face to business that every gentleman should. You'll feel better, look better and be time and money ahead. Just clip the coupon, pin a dollar bill to it and mail at our risk.

GUY de MAUPASSANT

King of All Short Story Writers

8 Volumes, Illustrated. *Size, 4½ x 7 inches*

Over 200 Complete Stories and

Pearson's Magazine

FOR ONE YEAR

Only $3.60 delivered FREE

Most Exceptional Offer—LIMITED NUMBER

FRENCH AUTHORS have written many lively tales which, because of false conventional modesty, have been, until recent translations, unknown to those who read only English. Prudish modesty and unfair prejudice have deprived us of the merriest and liveliest tales ever written. Maupassant was the one man in France who, because of his environment and temperament, could write truly the realistic scenes of **REAL PARISIAN LIFE** so fascinatingly as to rivet your attention to his merry tales, to the exclusion of everything else.

¶ **Maupassant's eventful career** gave him ideas, situations and local color for his unsurpassed stories. Strong in imagination, overflowing with natural enthusiasm and passion in his study of human life and phases of human conduct, things really happening—not as we imagine they might or as we would—**BUT THE REAL DOINGS OF LIFE** is what Maupassant always gives us. ¶ Poe describes the unusual, the unnatural, the impossible. Maupassant the real, the natural and the possible, holding a mirror up to nature. His dramatic instinct, his situations and his climaxes are overwhelming. He always fixes upon the one thing of most human-soul interest and makes it as vivid as any stage scene. These absorbing stories should be in every library—**tales of travel, mystery, adventure, comedy, pathos and tragedy, love and realism.**

¶ **EIGHT BEAUTIFUL VOLUMES of the Most Fascinating Reading in the World.** Contain over 2,500 pages, more than 300 pages to the volume, printed from a new cast of 8 point type, large and clear, on pure white antique paper made specially for this edition. Pages are wide with liberal margins, illustrated with specially made line-cut frontispieces, bound in de luxe art cloth, backs and sides stamped with an ornamental design.

¶ **WE GUARANTEE** that this edition is the first printing from brand new type and illustration plates.

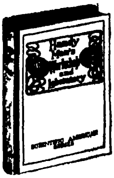
THREE NEW BOOKS JUST PUBLISHED BY MUNN & CO.



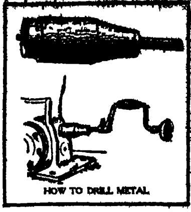
HANDY MAN'S WORKSHOP AND LABORATORY

COMPILED AND EDITED BY

A RUSSELL BOND

12mo 467 Pages. 370 Illustrations. $2.00 Postpaid

EVERY practical mechanic whether amateur or professional has been confronted many times with unexpected situations calling for the exercise of considerable ingenuity Some time ago it was decided to open a department in the Scientific American devoted to the interests of the "Handy Man" There was an immediate response from amateur and professional mechanics all over the country who sent in thousands of suggestions. The best of these have been prepared for use in the present book and a large portion of them has never before been published It may be regarded as the best collection of ideas by resourceful men Not only amateur mechanics, but professional men as well will find in this book hundreds of ingenious ideas, wrinkles or "kinks," as they are called The electrician the physicist and the chemist have all furnished their quota of ideas.



HOW TO DRILL METAL.

BRIEF TABLE OF CONTENTS

Chapter I Fitting up a workshop.—Building the shop the work bench the tool grinder the lathe the scroll saw the drill press, etc

Chapter II —Shop "kinks"—Thread cutting without a die, how to coil a spring, substitutes for a pipe wrench methods of driving a nail drills and methods of drilling, sawing holes in metal, home-made micrometer turning a ball etc

Chapter III Soldering of metals and the preparation of solder and soldering agents.

Chapter IV —Handy man in the factory.—Emergency uses of the lathe, milling machine etc

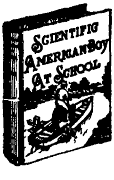
Chapter V —Handy man's experimental laboratory —Home-made laboratory apparatus, electric pendulum chemical experiments, home made seismograph etc.

Chapter VI —Handy man's electrical laboratory —Static electric apparatus and experiments, storage and dry batteries, home-built motors, an electrolytic rectifier wireless telegraphy etc.

Chapter VII.—Handy man about the house —Decorations and ornaments, electrical fountain cooler iceless refrigeration, milk testing without apparatus, home-made vacuum cleaner, how to mend garden hose, etc.

Chapter VIII.—The handy sportsman.—Portable automobile house, converting a buggy into an automobile, auto repairs, a one-man airship a Chanute type glider, ice yachts, scooters, installing a motor in a boat, bicycle coasting sled, reducing the range of a rifle.

Chapter IX.—Model toy flying machines.—Monoplanes, biplanes, an aeroplane kite, Diabolo flying machines, etc.

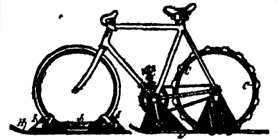


SCIENTIFIC AMERICAN BOY AT SCHOOL

BY A RUSSELL BOND

12mo. 338 Pages. 314 Illustrations. $2 00 Postpaid

THE present volume is a sequel to "THE SCIENTIFIC AMERICAN BOY" of which many thousands have been sold, and it continues the narrative and describes the construction of various devices and apparatus with particular reference to outdoor use. The constructions are fully within the powers of the average boy and the text is written so clearly that there can be no failure if attention is paid to detail. The list of chapters below gives an admirable epitome of the contents.



ANY BOY CAN CONVERT HIS OLD BICYCLE INTO A BICYCLE SLED

BRIEF TABLE OF CONTENTS

Chapter I —Initiation

Chapter II Building a dam

Chapter III Boat building.—The construction of a bateau

Chapter IV The club house on the lake —How to chop down a tree constructing a platform in the lake building a lake house

Chapter V —A chapter of surprises.

Chapter VI —The Modern Order of Ancient Engineers.—The pantagraph, the work bench an Egyptian lathe bow drill twisted cord drill

Chapter VII —A pedal paddle boat —A boat fitted with paddles driven by a bicycle.

Chapter VIII.—Surveying the Lake —An under water stockade surveying with the thumb with a ruler with a pin, with a 2 foot rule measuring heights by shadows and by reflection plane table surveying intersection and traversing

Chapter IX.—Sounding the lake —Method of taking and recording the soundings, a camera as a telescope, making a telescope.

Chapter X —Signaling systems. The ball cone and drum code the semaphore system, night semaphore and electric signals, the cipher disk

Chapter XI —The Howe truss bridge —A plank bridge construction of the Howe truss the snowball catapult

Chapter XII —The seismograph. Construction of a simple instrument for recording earthquakes

Chapter XIII —A canal lock.—Inclined elevators, construction of a lock for small boats construction of a drawbridge.

Chapter XIV —Hunting with a camera —An electric shutter the umbrella blind, climbers, under water photography

Chapter XV —The gliding machine

Chapter XVI —Camping ideas.—Sleeping bags, pine beds, fireless cookers, iceless refrigeration, water proof matches

Chapter XVII —The haunted house

Chapter XVIII.—Sun dials and clepsydras —Square faced dial vertical dial water clock

Chapter XIX Fish tail propeller —A new form of propeller for small boats

Chapter XX —Kite photography Triggers for springing the camera shutter telephone kite signals.

Chapter XXI —Water kites and current sailing.—A removable keel, sailing with a drag.

Chapter XXII A canvas-covered wooden canoe -Steam box for bending the ribs.

Chapter XXIII.—The bicycle sled

Chapter XXIV —Magic —An Egyptian entertainment, sleight of hand tricks.

Chapter XXV —The sail boat —Construction of a small sloop leeboards

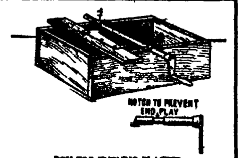
Chapter XXVI —Water sports —Dredging a swimming hole outdoor gymnasium swimming sail, human fish sea serpent.

Chapter XXVII —The geyser fountain.—A siphon fountain, concrete basin.

CONCRETE POTTERY AND GARDEN FURNITURE

BY RALPH C DAVISON

16mo. 196 Pages. 140 Illustrations. $1.50 Postpaid



NOTCH TO PREVENT END PLAY

BOX FOR TURNING PLASTER

THIS work should appeal strongly to all of those interested in ornamental concrete as the author has taken up and explained in detail in a most practical manner the various methods of casting concrete into ornamental shapes. The titles of the thirteen chapters of which the book is composed will give a general idea of the broad character of the work The first two chapters explain a most unique and original method of working pottery which has been developed by the author They are entitled

I Making Wire Forms or Frames. II Covering the Wire Frames and Modeling the Cement Mortar into Form The remaining eleven chapters are as follows III Plaster Molds for Simple Forms. IV Plaster Molds for Objects Having Curved Outlines V Combination of Casting and Modeling—An Egyptian Vase VI Glue Molds VII Colored Cements and Methods Used for Producing Designs with Same VIII Selection of Aggregates IX Wooden Molds—Ornamental Flower Pots Modeled by Hand and Inlaid with Colored Tile X. Concrete Pedestals. XI Concrete Benches XII Concrete Fences XIII Miscellaneous, including Tools, Waterproofing and Reinforcing The chapter on color work alone is worth many times the cost of the book inasmuch as there is little known on this subject and there is a large growing demand for this class of work. The author has taken for granted that the reader knows nothing whatever about the material and has explained each progressive step in the various operations throughout in detail. These directions have been supplemented with half tones and line illustrations which are so clear that no one can misunderstand them.

Switzerland. The German cards were printed without the impression of a stamp until 1872, in which year also the first private post cards were issued, in Germany. At the postal congress which met at Berne in 1874, and at which 22 countries were represented, the international post card of the value of 10 pfennigs, 12½ centimes, 1 penny, or 2 cents was adopted. The post card soon became popular and its use extended to other countries. Post cards are now issued in great numbers by 22 governments. In Germany alone more than 1,500 million post cards are used annually.

The private picture post card, which has attained such amazing popularity within the last decade, is nearly as old as the government post card. It is also of German invention and it owes its origin to the Franco-Prussian war. On July 16th, 1870, the first illustrated post card, bearing the picture of a gunner, was placed on sale by Schwartz, in Oldenburg. The manufacture of picture cards was afterward taken up by Brandt in Dresden. The industry, which is still carried on chiefly in Germany, has developed to gigantic proportions. Although many of the cards are striking examples of bad taste and vulgarity it cannot be denied that the best of the so-called art cards and the reproductions of famous paintings and statues have extended the love for the beautiful and that the landscape views have given to many persons some idea of the beauties of their own and foreign lands of which they would otherwise have remained in ignorance.

◆

Expenditure of Muscular Energy in Bicycling.

Bulletin 208 of the U. S. Department of Agriculture contains a description of experiments made by Profs. Benedict and Carpenter, of Wesleyan University, on the expenditure of muscular energy in bicycling. The chief result of the experiments, which were conducted with the aid of the respiration calorimeter, is that in bicycling the muscles of the legs work with an efficiency of 20 to 22 per cent, or, in other words, for each unit of heat produced by the external work of the muscles about four units of heat are lost by radiation, in addition to the heat so lost when the body is at rest. The external work was measured by an ergometer, consisting of a bicycle, the rear wheel of which was replaced by a copper disk, which rotated between the poles of an electromagnet, forming an electromagnetic brake. By this means the work was consumed in the production of induced currents in the disk and was ultimately converted into heat, which was measured by inclosing the whole machine in the calorimeter. The rider was then inclosed, with the machine, in the calorimeter and the heat produced in a definite interval of time was again measured. This heat was made up of three parts; the heat generated in the body in consequence of its muscular activity, the heat which would be evolved in the same time by the body at rest, and the heat produced in the ergometer by the external work of the muscles. The last-named portion had been measured in the preliminary experiment already described, and the second portion was measured by inclosing the man at rest in the calorimeter. These portions having been subtracted from the total quantity of heat produced in the main experiment, the remainder represented the heat generated in the body in consequence of the activity of the muscles employed in bicycling. This remainder was found to be about four times the heat generated in the ergometer, whether the bicyclist worked moderately or strenuously and whether he was experienced or not. Training, therefore, appears to have little effect upon the thermo-dynamical efficiency. It has long been known that the human body is a highly efficient engine, but it should be noted that the high efficiency of 20 to 22 per cent, exhibited in these experiments, has been exceeded by the Diesel and [illegible] [illegible] [illegible] motors.

WANTED.—One third-class mechanical draftsman at [illegible] per diem. A competitive examination will be held November [illegible], 1909, to fill the above position. For further information address "Commandant, Navy Yard, Norfolk, Va."

WANTED.—One first-class laboratorian at [illegible] per diem. A competitive examination will be held November [illegible], 1909, to fill the above position. For further information address "Inspector of Ordnance in Charge, Naval Torpedo Station, Newport, R. I."

Copyright, 1909, by Munn & Co., Inc.

The
Middle West
Number
of the
SCIENTIFIC AMERICAN

On December 11th, 1909, the Scientific American will issue a number devoted entirely to the wonderful Middle West region of the United States, a number which will set forth broadly and lucidly not only the agricultural interests of that region, but also those larger engineering undertakings which are destined to transform the Middle West, in part at least, into a manufacturing territory.

With that object in view the Middle West Number will publish articles on the following subjects:

I. The Chicago and Gulf Waterway.—An illustrated description of Chicago's drainage canal, an engineering work which stands without a parallel in the world.

II. Chicago as a Railroad Center.—Chicago is the greatest railroad center in the world.

III. The Wonderful Grain Trade of Chicago.—Chicago is an enormous wheat bin, into which much of the grain raised in the middle West is poured.

IV. Shipping on the Great Lakes.—Most of the iron ore that is now smelted in Pennsylvania is mined in the middle West. To transport it to the blast furnaces of the East at a cost which will enable American steel makers to compete with foreign steel makers, it has been necessary to devise a new kind of lake transportation. Ships of [illegible] and [illegible] tons burden have been constructed which convey ore at small cost through the Great Lakes, and which are without a counterpart anywhere in the world.

V. The Handling and Shipment of Iron Ore.—The above-mentioned fact that iron ore is mined in the middle West and smelted in the East has necessitated not only the construction of special freight-carrying steamers, but also the designing of special machinery for loading and unloading the ore from the steamers.

VI. Freighting on the Mississippi.—Freighting on the Mississippi is a more important industry than most of us may realize.

VII. The Steel Industry.—One of the greatest steel plants in the world is that which has been built at Gary.

VIII. The Freight Subway System of Chicago.—Chicago can boast of a rational system of handling freight by means of subways.

IX. The Water Supply of Chicago.—Chicago's source of water is Lake Michigan. The city is supplied with water by means of a tunnel which extends two miles out into the lake.

X. Reclaiming Arid Lands.—The United States Government has under way many irrigation projects for the purpose of reclaiming lands which are arid but which will blossom if properly watered.

XI. Harvesting the Grain of the Middle West.—Farms that cover not acres but square miles, crops that aggregate not simply bushels, but car-loads, have rendered it necessary to plant and harvest on an unprecedented scale in the middle West. The ingenious agricultural machinery which has been designed to cope with these peculiar conditions is described and illustrated.

The Middle West Number will be more than twice the size of the regular SCIENTIFIC AMERICAN. It will be lavishly illustrated. It will be contained in a colored cover which strikingly depicts Chicago's grain elevators at work. Order from your newsdealer or from

HAVE YOU

ever stopped to consider that

JUDGE

has for twenty-seven years been an honored guest of nearly every prominent club, every recognized men's organization, public library, reading room and hotel in the United States?

Have you ever stopped to consider that JUDGE is welcomed in every home, irrespective of its race, creed, religion or politics, and is agreeably welcomed by every member of the family? Men, women and children all find everything to amuse and entertain in its clean, bright columns and nothing to offend.

MR ADVERTISER

Be your product what it may, you are certain to find among the increased JUDGE family some large number of readers who are ready and waiting for your message with ample means for accepting it.

Consider too the long life of JUDGE. A single copy of JUDGE will pass through the hands of more readers than any other publication you can name and then will be preserved.

JUDGE has the largest circulation of any weekly of its class. It is not only a club paper, but a medium of national circulation, appealing to every member of the family, read and reread again.

Your advertisement, read during their leisure moments, is sure to secure the attention of the people you want to reach.

Try Kerosene Engine
30 Days Free

Gasoline Prices Rising.

You can't run a farm engine profitably on gasoline much longer. Price of gasoline going sky high. Oil Companies have sounded the warning. Kerosene is the future fuel and is now 6 to 10c a gallon cheaper than gasoline. The Amazing Detroit is the only engine that uses common lamp Kerosene (coal oil) perfectly. Runs on gasoline, too, better than any other. Basic patent. Only 3 moving parts. Comes complete ready to run. We will send a Detroit on free trial to prove all claims. Runs all kinds of farm machinery, pumps, saw rigs, separators, churns, feed grinders, washing machines, silo fillers and electric lights. Money back and freight paid both ways if it does not meet every claim that we have made for it. Don't buy till you get our free catalog. 2 to 24 h. p. in stock. Prices $[illegible] up. Special demonstrator agency price on first outfit sold in each community. [illegible] satisfied users. We have a stack of testimonials. Write quick. [illegible]

Salesmen Wanted

We receive calls for thousands of Salesmen and have assisted thousands of men to secure good positions or better salaries. Hundreds of them who had no former experience and who formerly earned from $40 to $75 a month, now earn from $100 to $500 a month and all expenses, and some even more than that. No matter whether you are a new beginner or an old hand at the game, our eight weeks course in Salesmanship by mail will enable you to increase your earning power from two to ten times what it is at present. Our FREE EMPLOYMENT BUREAU will assist you to get a good position. Marshall Field, the great dry goods merchant of Chicago; Ex-Postmaster General John Wanamaker, the great merchant of New York and Philadelphia, and scores of other famous and wealthy men got their start selling goods on the road. Your chance is as good as theirs was. Thousands of Traveling Salesmen earn from $2500 to $10,000 and up as high as $25,000 a year. If you are ambitious and want to enter the best paid profession on earth, fill out coupon and send for our free book, "A Knight of the Grip," today. It will tell you how to do it. Address Dept. 465

PURITY OF CATSKILL WATER SUPPLY

The special experts on the purification of water for the New York Board of Water Supply have been investigating local conditions at the Ashokan Reservoir with a view to determine whether the surface soil and vegetation on the bottom and sides of the Ashokan Reservoir should be entirely stripped down to the clay and gravel, as was done in the larger reservoirs of the metropolitan water districts of Massachusetts or whether some other treatment to obviate deterioration during storage was preferable It was estimated that the stripping of the soil would cost about $5,000,000 Messrs Hazen and Fuller the expert engineers, have decided that the stripping of the Ashokan Reservoir would not prevent tastes and odors in the water to a sufficient extent to warrant the great expenditure They considered that aeration at a small fraction of the cost of stripping the reservoir would result in better water, and that perfectly satisfactory water can be obtained by both aeration and filtration whether the reservoir is stripped or not It was recommended that all the trees and bushes over the entire area be cut close to the ground and burned shortly before the area is flooded and that all the stumps and roots be taken out, so that in case of low water they would not be unsightly They also recommend that at the outlet of the reservoir a large fountain be built where all the water drawn out will be thoroughly exposed to light and air

THE NEW FOURTEEN-INCH ARMY AND NAVY GUNS

Great interest attaches to the new 14 inch gun for the navy which has been delivered at the navy yard at Washington where it will be rifled and the breech mechanism installed On completion it will be shipped to the naval proving grounds at Indian Head Maryland for a test The completed gun will weigh about 63 tons, its projectile will weigh about 1 400 pounds and the latter will be propelled by a charge of 365 pounds of powder The extreme range at maximum elevation will be more than twenty five miles As compared with the present navy 12 inch gun, this will be a far more powerful weapon It will penetrate any armor afloat, at the most distant ranges at which accurate aiming is possible The army has also a 14 inch gun of much lower velocity and power which will soon be tested at the Sandy Hook proving grounds The lower muzzle velocity (about 2 000 feet per second) of the 14 inch gun will give it additional life over the 12 inch gun After some eighty discharges the rifling of the present 12 inch gun of 2 500 foot-seconds velocity becomes so badly worn as to destroy the accuracy In the case of the 14 inch gun the erosion is much less and the gun will be serviceable for about 300 discharges.

THE NEW BRITISH AND GERMAN "DREADNOUGHTS."

The biggest Dreadnought of Great Britain and the most powerful German vessel of the same type were put into the water on the same day The "Neptune," the English vessel, has a displacement of 20,250 tons, will carry ten 12 inch guns and twenty 4-inch guns, and her total broadside will weigh 9,120 pounds The German "Dreadnought" "Ostfriesland" has a displacement of 19,000 tons, will carry twelve 12-inch guns, twelve 6.7-inch guns, and twenty-two 4-inch guns, and she will deliver 14,204 pounds in a single discharge of all her guns. The most remarkable feature of the "Neptune will be the extraordinary power of concentrating the gunfire. The ten 12-inch guns will be mounted in pairs in five barbettes. One barbette will be placed in the forecastle on a high level. The two broadside barbettes will be *en échelon*, that on the port side being more forward than the barbette on the starboard side. By a novel arrangement the superstructure is bridged over these two barbettes, both pairs of guns being fired on either side at once if required Of the two barbettes astern, one will be raised above the other so that all four guns can be fired direct astern simultaneously The broadside fire of the Neptune will thus be ten guns, the stern fire eight guns, and the direct-ahead fire six guns The "Ostfriesland,' on the other hand, has four of her twelve guns masked by the superstructure, and can fire only eight 12 inch guns on either broadside Her end-on fire will be six guns ahead and astern

ACCELERATION OF LONG-DISTANCE EXPRESS SERVICE.

Hitherto the trip from New York to St. Louis has been a rather trying one Now, however, conditions are ameliorated by two through trains which make a schedule run from New York to St. Louis in twenty-four hours The New York Central train leaves at 2 45 in the afternoon, and the Pennsylvania train at 6 25 P M The Central's train is a duplicate of the "Twentieth Century Limited, and the Pennsylvania's is a duplicate of its eighteen hour "Chicago Flier" The Central train is due to arrive in St. Louis at 1 45 P M, which allowing for the difference in time makes a run of just twenty four hours. The time saved is about five hours and both of the trains are luxurious in the extreme There are now seventeen trains daily each way on the New York Central and Pennsylvania systems.

THE LIMIT OF RAPID TRANSIT

If all mechanical difficulties could be overcome and sufficient horse-power could be developed, what would be the minimum time in which passengers could be transported say from New York to Philadelphia? At first glance, one is apt to overlook the fact that the freight to be transported is not mechanical, but human and this is a very important factor in the problem because the safety and comfort of the passengers must be considered It is really a question of starting and stopping that imposes a limit on the reduction of time consumed in transit A very interesting discussion of the question has been received from one of the readers of the SCIENTIFIC AMERICAN He points to the fact that the quickest way to get from one place to another without shock or jar is to travel faster and faster until half the distance is covered, and then to slow down until the destination is reached When the rate of acceleration is just such as can be borne with comfort, the limit is attained The effect on the passengers would be a continuous pressure against the back of the seat, of the sort experienced when a car is started suddenly for the first half of the journey and then in order to prevent them from pitching out of their seats the chairs would have to be turned in the opposite direction for the rest of the journey during which the same sensation would be felt If an attempt were made to make the same time by any other method involving uniform speed throughout the greater part of the journey an unpleasant jar or pressure would be experienced in starting and stopping The highest speed attainable would therefore be proportional to the distance traversed

Our correspondent draws a fanciful picture of the railroad of the future, which would permit of such rapid transit The trains would have to run in a vacuum to prevent them from being heated to incandescence by the resistance of the air They would also have to be held in suspension in the vacuum tube through which they travel, for the slightest contact with the sides of the tube would result in enormous friction The cars might be held in suspension by the repulsion of opposing magnets on the cars and tube respectively When thus isolated, they could be propelled only by the magic power of magnetism Under such conditions, the energy consumed in propelling the car would be quite low The running time on such a road between New York and Philadelphia or New York and Boston would be a matter of a few minutes The time for each half of the distances could be calculated from the well-known formula, $S = \frac{1}{2} a t^2$, where S is the distance, here *half* the whole journey, a, the acceleration, or change of speed each second, and t, the time in seconds. Taking an acceleration of 11 feet per second each second, which would bring to rest, in 4 seconds, a train moving at 30 miles per hour (44 feet per second) he finds that the time from New York to Philadelphia (85 miles) and from New York to Boston (190 miles) would be 6 minutes 44 seconds and 10 minutes 4 seconds respectively.

This may indeed be considered the absolute limit of rapid transit; for the passengers would be traveling each half of the distance one-third as fast as they could fall through the same space under the attraction of gravity

THE OTHER HALF OF THE CULLINAN.

It is reported in African papers that the original stone, of which the Cullinan was a portion, has been found in the possession of the Kaffirs of the Magatts tribe in Zoutpansberg. The dimensions of this second Cullinan stone have been given as 4,322 karats.

This story has been denied by the Transvaal Department of Mines, and an official of the treasury in Pretoria states that the origin of the legend can undoubtedly be traced to the belief that enormous quantities of diamonds were buried by command of the celebrated chieftain's wife Majatje during the Boer war These diamonds became the spoil of the Kaffirs when they returned to Kimberley But these treasures are lost, for the Kaffirs who buried them are dead and search for them has been without result.

The possibility of finding still larger stones than the Cullinan in the soil of South Africa is, however, by no means remote. G A. Molengraaff, professor of mineralogy in the Technical High School at Delft, recently stated that the Cullinan is only a portion of a much larger stone, the original form of which can only approximately be indicated Four pieces must have been broken off from the original stone by natural crystal cleavage, which is evident from the cleavage planes Each of these pieces must have been of considerable size. Accordingly, the natural end planes (called "nijf" in the language of the diamond workers) are only partially shown in the Cullinan Most of the crystal planes are cleavage planes. The original portion of the surface shows only a single octahedral face, it also has an irregular curved front surface bearing some resemblance to the six faces of a dodecahedron and a very irregularly formed cubical (hexahedral) surface in which the quadrangular impressions can be recognized These quadrangular impressions are characteristic of minerals such as diamonds, which occur in the octahedral form The Cullinan consists of a single crystal, there are no traces either of a twin crystal or of twin lamellæ, it is completely transparent and colorless Its transparency can be best compared with that of very pure ice or with the complete clearness of the variety of opal known in the mineral kingdom as hyalite (principally consisting of silicic acid) It is true that the Cullinan contains a few impurities in the shape of inclosed grains, also some internal cleavages of fragmentary character called "glessen" in the Dutch diamond trade but their situation is such that they do not injure the value of the stone as a jewel. In any case the Cullinan is the purest of all large precious stones hitherto found

The question now arises whether there is a possibility of finding the pieces broken off by crystal cleavage That they can be found is certain but it is impossible to predict whether they are now in diamond mines or elsewhere The diamond is formed, as is known at great depths by the decomposition of carbon, dissolved in the molten basic plutonic magma of the earth (The so-called blue-earth' is formed at a later period from this rock.) The carbon was then, under enormous pressure and at the very high temperature prevailing at these depths, deposited from the molten rock in the form of diamonds During the volcanic discharges of the masses of rock the diamond was forced upward with tremendous force and the very great friction to which the mass was exposed during its passage through the crater shaft caused the cleavage of the stone according to crystallographic laws to which we have referred It is therefore not impossible that the broken-off fragments of the Cullinan are scattered over a wide space, and that they may one day be found on the surface of the earth, but it is just as possible that they are still reposing in the depths of the mines Sir William Crookes has also lately expressed the opinion that the Cullinan is the smaller portion of an octahedron broken by crystal cleavage

◆

New applications of electricity are being discovered daily but not every new application is of as much interest or importance as one recently developed for purifying the air of reading rooms, theaters, and other close places where large numbers congregate. The apparatus referred to is the ozone generator installed recently in the Chicago Public Library to purify or ozonize the 10,000 cubic feet of air per minute that is forced into the main reading room After the installation of the ozonizing apparatus it was found that the main reading room was completely deodorized, the air being freed of that disagreeable and deleterious odor which for years had so thoroughly permeated all papers, books, furnishings, etc., in this large room. The fresh sterilized "mountain" air in the room reduced the humidity during the hot, oppressive days of summer, and greatly increased the comfort of the readers and employees. The installation renders the disinfecting of all books, periodicals, papers, etc., on the shelves, racks, tables, etc., an automatic process, keeping them constantly in a hygienic condition.

ENGINEERING.

The North British Locomotive Company has recently completed and tested the first steam turbine locomotive, and it is said to be entirely successful.

The great shops of the Pennsylvania Railroad Company at Altoona, employing 13,000 men, are now working full time. This is the first time since the financial depression of 1907 that all departments of the great shops have been operated.

A non-shrinking alloy can be produced by melting together 50 pounds of tin and 50 pounds of zinc This gives a hard alloy if a good grade of zinc is used Two pounds of bismuth will render it very fluid and enable it to be poured at a lower temperature

Work is being pushed on the Cape Cod Canal A big granite breakwater is being constructed in Cape Cod Bay to protect the end of the canal and furnish anchorage for shipping. At the other end, in Buzzard s Bay, work is also proceeding at a fair rate

A new trolley car is being experimented with in New York city The new car is operated by gasoline, and is also supplied with an electric equipment. In the event of a blockade or accident on the road, the new cars can be switched over to another track and be run by gasoline. Riding in the car is very much like riding in an automobile, there being an entire absence of the jerk which is so disagreeable in electric cars. The radiator is on the roof

A twenty-four-hour test of the 'North Dakota" at a 12-knot speed was finished November 7th The consumption of coal and water was well below the guaranteed mean amount. The consumption tests of this battleship are therefore in keeping with the remarkable speed shown in her special mile trials. It has been found that her turbine engines have developed a greater top speed and generated power for a low speed at less expense for coal and oil supplies than did the reciprocating engines of the "Delaware"

The Board of Estimate of the City of New York has approved the action of the Public Service Commission in awarding contracts for the construction of the Fourth Avenue subway in Brooklyn and work on this very much needed improvement will proceed at once The contracts were sent to the Board of Estimate over a year and a half ago, and have been held up ever since. As the building of subways under the best conditions cannot keep pace with the increase in population, it is to be hoped that there will be no such senseless delays in authorizing future subways

An exhibition was recently made of Mr Louis Brennan's monorail car which, it will be recalled, is held in upright position by means of gyroscopes. Since the first announcement of his invention, Mr Brennan has been at work developing the car to practical dimensions and the present model is large enough to contain forty passengers. The car was operated both on a straight and a circular track, and maintained its equilibrium perfectly So sensitive was it to the shifting of the center of gravity, that when the passengers all crowded over to one side, the car immediately righted itself and maintained its horizontal position. Mr Brennan overcomes the precession by means of frictional devices acting on the gyroscope wheels.

The Baldwin Locomotive Works has just completed for the Atchison, Topeka & Santa Fé Railway the most powerful passenger locomotive now in use Apart from its tender this locomotive weighs 376 450 pounds, and is 65 feet long. The tender carries 12 000 gallons of water and 4,000 gallons of oil, which will be used as fuel. The length of the locomotive and tender is 105 feet. The tractive power of the locomotive is 53,000 pounds. There are five pairs of driving wheels, 73 inches in diameter, working in sets of two, the locomotive being of the Mallet articulated type. The locomotive is the first for passenger service to be built of this type, and is the first to combine feed-water heater, superheater and reheater in one machine. Its firebox is built on an entirely new plan which eliminates staybolts.

The October Engineering Review gives an admirable illustrated account of the progress of work on the Los Angeles aqueduct, now about half completed It is probably little realized, away from southern California, that this is by far the largest hydraulic engineering work now in progress, with the exception of the Panama Canal It speaks well for the courage of the people of Los Angeles, and their faith in the future of their city and district, that they should meet by this immense undertaking the serious problem of a waning water supply coupled with a growing population. The aqueduct will be 250 miles long, and will be capable of conveying 260 million gallons of water per day from the Sierra Nevada across the Mojave Desert to San Fernando Valley, providing sufficient water for power purposes and irrigation of the district, as well as for the city supply. Practically the entire work, including tunnels, steel siphons, and concrete-lined and covered canal, is being done by the city under the direction of its own engineers.

ELECTRICITY.

The city of Baltimore is evidently favorable to municipal ownership The problem of lighting the streets is being investigated In September, 1910, the contract for lighting the city expires, and hopes are entertained that a municipal plant will by that time be ready to furnish power for the street lamps

Following a test of gas-electric motor cars between Manassas and Strasburg, Virginia, the Southern Railway Company has bought two of these cars from the General Electric Company Each car is equipped with a pair of 100-horse-power motors operated on a voltage of 600 The current is generated by an 8-cylinder gas engine The cars are 55 feet long and will seat 52 passengers.

The Third Avenue Railroad Company of this city is experimenting with gasoline-electric power on its 125th Street crosstown line. The requirements call for a car which can run up a five per cent grade and which can maintain a schedule of eight miles per hour with ten stops per mile. So far the results have been very satisfactory, the car has successfully run up an eight per cent grade and is keeping its schedule

The new Blackstone Hotel in Chicago is provided with an unusually complete electrical equipment. In the kitchen particularly extensive use is made of electrical labor-saving devices. There are electric dish elevators, dish washers, vegetable parers, dough mixers, silver-polishing machines etc The laundry of the hotel is also completely equipped with electrically driven laundry machinery of every description

Before the advent of the metallic-filament street lamp gas lamps were largely used in English cities to illuminate the side streets, as the requirements did not justify the use of flaming arc lamps. Now the gas lamps are giving way to the metal filament lamps which afford a considerable saving Nearly two thousand side street lamps at Marylebone have been changed from gas to electricity, with the result that $7 500 has been saved

The Railroad Commission of Indiana has been ordered to investigate the various types of headlights for locomotives and when the best one has been discovered, to require the use of this headlight on every railroad in the State The tests have recently been undertaken near Avon Ind to determine the relative efficiency of oil and electric headlights The effect of opposing headlights, the distances at which obstructions on the track could be detected and the effect of observing signals were investigated, but as yet no conclusions have been reached

A new form of electro-magnetic clutch has recently been devised in which a stationary electro-magnet is used to draw the clutch members together into frictional engagement The magnet coil is placed between flanges formed on the two members of the clutch and when it is energized it attracts the clutch members with sufficient force to permit one to drive the other When the current is cut off, a spring serves to separate the clutch members. The advantage of this system lies in the fact that the magnet does not come in contact with the parts it actuates

The Electric Railway Journal calls attention to the many problems which arose in modernizing the traction system of Bombay As the average daily income of the inhabitants is but 25 cents, five-cent fares are out of the question The fare is two cents for a seven mile ride, while the average fare is one anna or one and one-third cents In order to withstand the ravages of insects special varieties of wood had to be used in the cars and track system Even the overhead system had to be modified so as to permit of the passage of the tall shrines used by the natives in their religious pageants

Practically all the coal consumed in Brazil is imported As a consequence the cost of fuel is very high and this has done a great deal to prevent the growth of manufacturing industries. However advantage is now being taken of the water power of the country A recent consular report points out the development of hydro-electric power systems around Rio de Janeiro, showing that many manufacturing concerns are changing from steam to electricity and it is hoped that the industrial development will be largely increased because of the greater advantages and the economy of using electric power

The new articulated electric locomotives of the Pennsylvania Railroad for service in the New York and Long Island section virtually are two separate locomotives coupled together The motive power comprises a pair of 2,000-horse-power direct-current interpole motors, which are crank-connected to the driving wheels. The locomotives are required to start a 550-ton train on a two per cent grade and must have a tractive effort of 60,000 pounds Although a speed of sixty miles per hour was called for in the specifications, the locomotive now under test has made seventy two miles per hour. The weight of the locomotive is 332,160 pounds.

Lieut. E H Shackleton who returned from an Antarctic expedition early this year, after reaching a point within 111 miles of the pole, has been knighted by the King of England

Arrangements will shortly be made by the Austrian government for the public sale of radium for medical and experimental purposes The total quantity of radium which has been thus far recovered for scientific use throughout the world is estimated not to exceed a quarter of a pound

The Harvard Observatory announces that a photograph of the spectrum of Morehouse s comet taken on November 17th 1908 with an eight inch telescope shows six broad bright bands These bands appear to coincide with the hydrogen lines zeta epsilon, delta, gamma beta and the strong bright band at wave length 464 to 473 characteristic of spectra of the fifth type

Tantalum is a rare metal of slight importance the only practical use to which it is now known to be put being in making filaments for incandescent electric lamps The efficiency of the tantalum lamp is greater than that of the carbon lamp but somewhat less than that of the lamp with tungsten filament As more than 20 000 filaments of 20 candle-power can be made from a pound of tantalum the market is not large It is at present probably supplied by rich manganotantalates from western Australia No tantalum minerals are known to have been produced in the United States in 1908 according to F L Hess whose report on various rare metals forms an advance chapter of Mineral resources of the United States calendar year 1908 published by the Geological Survey The tantalum used in the manufacture of lamps in this country is made in Germany and imported at a cost of $ 00 or more a pound

A great daylight meteor of October 6th was observed by many persons in various parts of England The particulars to hand are not very definite and it is scarcely possible to compute the real path of the object From a comparison of about fifteen descriptions W F Denning states in Nature that there seems little doubt that the meteor moved in a direction from south to north over Reading Thame and on to a termination near Market Harborough The radiant point was in Leo and it is hoped that more observations of an exact character will be supplied The sky was clear over a large extent of England and hundreds of persons saw the meteor though only a small proportion of that number have reported their observations The great daylight meteor of 1900 January 9th was directed from Aquila that of 1894 February 8th emanated from Hercules It is seldom that meteors appearing at such times can be suitably observed as the sky does not afford any reference objects such as is furnished by the stars at night.

Before timber is subjected to preservative treatment it is customary to remove the bark Unless this is done very thoroughly however patches of the inner bark will remain on the wood Until recently it does not seem to have been realized that this bark presented a very effectual hindrance to the penetration of creosote The same thing was discovered by the management of one of the large creosoting companies in the South and steps were immediately taken to see that every particle of bark was removed from piling and other timbers While it is probable that the bark of all species is not as resistant as that of pine it is not known how the different species rank in this respect. In the creosote treatment of timbers it is rarely that the entire stick is penetrated by the preservative The value of the treatment consists largely in the creating of an exterior antiseptic zone around the untreated interior portion If this outer zone be broken the value of the treatment is to a large extent lost.

Recent investigations by the United States Geological Survey have shown that oxygen so essential to all life forms in coal an impurity that is almost as injurious as the ash content Oxygen and ash are of very nearly equal negative value ash being probably a little more injurious in most coals The calorific value of coals in general is indicated by the balance between the total carbon on the one hand and the sum of the two great impurities oxygen and ash on the other The practical application of these statements appears in considering the effect of the exposure of coal to the weather The weathering of the lower grades especially lignites, bituminous coals and peats is marked by the accession of oxygen which is taken into combination This increase of the oxygen content permits a calorific deficiency which on account of the high anticalorific value of oxygen is often serious. It is possible that in many cases considerable increase of oxygen and consequent loss of efficiency are suffered by the lower-class fuels between removal from the bed and consumption and it is probable that in the sub-bituminous coals and more especially in the lignites, oxygenation begins immediately after the coal is blasted from the face in the mine

SOMETHING NEW IN CONCRETE BLOCK MAKING

BY H. H. HUNTING

Of the many recent applications of concrete to the building industry in this country, few, if any, have attracted more attention than the process invented by a Des Moines Iowa, man for the manufacture of enameled concrete blocks A machine of gigantic proportions performs the many operations through which the block passes without the aid of the human hand, turning out 40 000 perfect blocks in each day of ten hours, each one an exact duplicate of every other in form and color

The machine is 13 feet 8 inches in height, 17 feet in length, 6 feet in width, and weighs over 70,000 pounds. In the accompanying illustrations a man is shown standing beside the machine. This comparison gives a good idea of the machine's great size

The process for the manufacture of the blocks as before stated is automatic from first to last The raw material, including cement sand, and gravel (or crushed stone), is first screened, and then workmen separate the aggregates into several sizes to eliminate voids and give added strength to the finished product.

The ingredients are then mixed dry, after which a sufficient quantity of water is added to bring the mixture to a proper consistency This mixture is then fed into an agitator, where it is kept under continual motion and permitted to flow into eight individual scale hoppers, each weighing the exact amount of material required for a single block. Then in unison those hoppers are dumped through receiving spouts into the molds which form the block, these being prepared in advance for the reception of this material

While the above process is going on, a similar one for the preparation of the material forming the enameled part of the block is taking place in another part of the machine. This also starts by taking a dry mixture from individual bins, and measuring it automatically in a receptacle known as the reserve tank At this time also the proper amount of coloring matter is added, so that blocks of a uniform shade may be produced.

Any color or combination of colors may be used, and no matter whether one, one hundred, or one thousand blocks are made, the same shade is produced in each one

Water is next added after being automatically measured, and from the reserve tank the material is discharged into a receiving tank, a part of the machine proper with which are connected eight dipping cups conveying the material in a liquid form to the individual molds.

The molds are now ready for the body material, which has been in preparation as already described, and with the next movement of the machine an intimate association is effected between the two by the enormous pressure of 3,200,000 pounds applied to produce perfect cohesion

A CONCRETE BLOCK MACHINE WEIGHING 70,000 POUNDS.

The molds move forward until they reach the releasing section of the machine, where the blocks are ejected, eight at a time, upon a pallet and loaded intact by workmen upon a car especially constructed for the purpose.

They are now conveyed to suitable storage, where they are allowed to season, no burning being required Nature finishes the work by a process of crystallization, which gives each block a perfect surface without danger of distortion, as commonly results from burning clay bricks.

The illustration shows the machine to consist of a rotary carrier consisting of thirty mold frames, each containing eight individual molds. At each movement of the machine several of these molds are receiving material at various fixed points, one group the enameling material, one the body material, while a third is submitting to the tremendous pressure which unites the two. After the application of this pressure, the next motion delivers the blocks contained in one mold frame upon the pallet as described elsewhere.

Anyone familiar with the process of manufacturing clay brick will readily realize the tremendous saving of time and expense accomplished by this process of manufacture. It has been estimated that the cost of sorting clay brick for quality and color is not less than $6 per thousand This work of course is entirely done away with, as the enameled concrete blocks are absolutely uniform as to size and shape, and there can be no variation in color.

While especially designed for the manufacture of blocks, this is not the only function of the machine. Tile of various shapes, sizes, and colors are also produced by it with equal facility

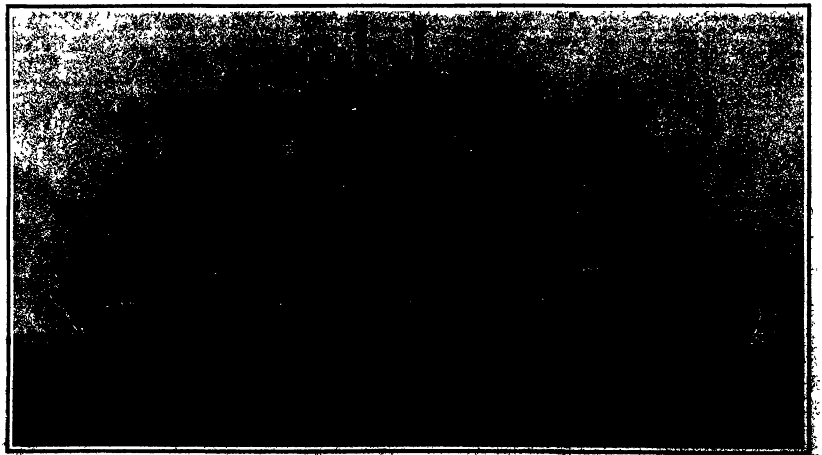
Though not in general use thus far owing to the inability of the manufacturers at the present time to supply the demand, the machine has nevertheless received exhaustive tests, and in each has given entire satisfaction. As for the material it produces, there can be no doubt as to its becoming popular. Our forests are rapidly disappearing, stone is prohibitive because of its expense, and the prospective builder turns with satisfaction to this comparatively new material, which recommends itself not only because of its cheapness, but because of its great lasting qualities.

A "DREADNOUGHT" OF 1863

[The correspondent who sends us the photograph of an engraving from which the accompanying illustration of the "Roanoke" is reproduced, believes that this United States warship is entitled to be considered as the prototype of the modern "Dreadnought." We doubt if any early vessel can be quoted as having a stronger claim to be regarded as the first warship of this type.—Ed.]

To the Editor of the SCIENTIFIC AMERICAN

In the battleships of the "Lord Nelson" class of 1906, the British had come to about the limit of their intermediate battery, which consisted of ten 9 2-inch guns, these being substituted for the four 9 2 and ten



The frigate "Roanoke," subsequently to the civil war, was reconstructed at the Brooklyn navy yard. Her masts were removed; her sides armored; and her [illegible] by an all-big-gun armament of six heavy guns mounted in three armored turrets. The correspondent who sent us the above illustration suggests that she was the first of the [illegible]

U. S. S. "ROANOKE," 1863. IS THIS THE PROTOTYPE OF THE MODERN "DREADNOUGHT"?

which of the "King Edward VII." class launched three years previous. In this same year they also launched their first "all-big-gun" ship, the "Dreadnought," by abolishing the 9.2-inch guns, substituting in their place six 12-inch guns, and adding these to the four 12-inch guns, which the other two classes already had, making ten in all, and placing them in pairs in five turrets. This is the ship that in three years has revolutionized the navies of the world, all of whom are now building this class known as "Dreadnoughts." But was not this idea of the "all-big-gun" ship taken from one that was first produced in the American navy?

The definition of a "Dreadnought,' as I understand it, is an armored ship with a high freeboard, carrying only guns of the largest caliber in use, these arranged on one deck in pairs and in armored turrets, the number of turrets not being restricted necessarily to five, can be one more or one less according to the tonnage of the ship.

In 1852 there was a steam frigate built by the United States at the Gosport navy yard at Norfolk, Va., and called the "Roanoke." She was 265 feet in length, with a breadth of 52½ feet, and a depth of 26. Her machinery was built by the Tredegar Iron Works at Richmond, Va., and consisted of a pair of trunk engines with cylinders 72 inches diameter and 26 inches stroke.

This frigate was anchored in Hampton Roads at the time of the battle between the "Monitor" and "Merrimac." After this fight, which introduced to the world the revolving armored turret with its pair of heaviest guns afloat (15-inch smooth-bores) she was taken to New York and rased at the Brooklyn navy yard Her masts and sails were removed, her sides were armored, and she was equipped with three Ericsson turrets at the Novelty Iron Works in 1863. Each of the turrets contained a pair of the heaviest guns in use, and they were placed fore and aft on the center line of the vessel, which is the arrangement of the turrets on American "Dreadnoughts." The vessel had no masts and no secondary or auxiliary battery, only the "all-big-gun" armament.

It seems to me that the "Roanoke" complies in every way with the definition of the modern "Dreadnought", that the idea of the "Dreadnought" was first developed in her, and that she was the first "Dreadnought"—or in other words, the great 'Dreadnoughts" are developed "Roanokes" Their arrangement of guns, armor, and turrets is from her The "Roanoke" had no military or skeleton masts or rapid fire guns, these at that time not being necessary, as wireless telegraphy and torpedo boats were not then known.

The American navy had the first steam vessel of war and the first 'Monitor," and should it not be credited with the first "all-big-gun" ship, the "Roanoke," of which the "Dreadnoughts" are but an enlargement of the same idea? I inclose a photograph of the "Roanoke," taken from a large lithograph made for the Navy Department, and presented to me by the Assistant Secretary, G V Fox, with a number of others in 1863.

William Bosbum Wetmore.

Allenhurst, N J

POWER INDICATOR FOR INTERNAL-COMBUSTION ENGINES.

A strikingly novel instrument, the invention of Prof N Monroe Hopkins of the George Washington University, is pictured in the accompanying engravings. The instrument is a combination power indicator and precision speedometer without a flexible shaft, and when the equipment is installed upon a stationary engine, automobile, motor boat, or aeroplane, shows what the cylinders of the engine are doing separately or together, which, if any, cylinder is missing, the power of the engine and the conditions under which it is doing the most useful work, how to adjust the carbureter perfectly when the engine is idle as well as under load, speed with absolute precision from 1 to 60 or 100 miles per hour, and mileage, and the revolutions per minute of the propeller in aeroplane and marine work

Interior details of the indicator

The instrument is an original application of the fact that an electric current is produced by the simple heating of the junction of two dissimilar metals, and the magnitude of the current so generated is proportional to the junction temperature

Ordinary thermo-couples as evolved by Becquerel, and used for general temperature measurement in the arts and sciences, would never "live to operate under the high temperature and peculiar chemical conditions in a gasoline engine cylinder, because they would become so heated as to preignite the charge and cause the gas engine to buck, hitch, or back fire and in addition would become brittle and drop apart either through oxidation or the absorption of carbon after a short period of use Actual temperature measurements by means of thermo-couples or thermometers could not be made in gasoline engine cylinders

Prof Hopkins's thermo-couples are of original construction and are designed to give an idea of the temperature in a gasoline engine without actually attempting to measure it. His instrument faithfully and continuously shows, by modified temperature readings, the working conditions of gasoline engine cylinders. The 'thermo-plugs give the same electrical pressures after 50 000 miles use on an automobile as when first applied

One of the illustrations shows a sectional view of a combination firing and indicating plug The thermo-couple may be seen at *A* It consists of special alloys drawn into wires surrounded by massive metal tubes closely fitting the wires and adjustably receiving them These metal tubes are connected at their upper ends through the agency of heavy metal lugs connecting with the binding posts and dissipate the heat by conducting it at a predetermined rate away from the tip of the thermocouple within the engine cylinder to the binding posts without All plugs are calibrated and are interchangeable The adjustment in such plug being obtained by sliding the thermocouple wires through the heavy metal tubes to a greater or lesser distance into the engine cylinder Stuffing boxes screw on to the top of the metal tubes making a gas tight joint between the thermo-couple wires and said tubes. In practice they protrude beyond the lower end of the metal tubes about 3/64 of an inch.

An engine should have these specially constructed thermo-couples in each spark plug They may be selectively or collectively connected with an electrical indicating instrument which gives an accurate reading of the current delivered by one particular cylinder or by the combined cylinders if the spark plugs be connected in series

There is a switch on the instrument for obtaining separate or combined cylinder indications The instrument has two scales the upper a speed scale and the lower a power scale On the switch there is also a speed contact *S* which connects a small magneto-dynamo with the indicating instrument and electrical current is furnished in direct proportion to the speed at which the dynamo is driven In addition to this com

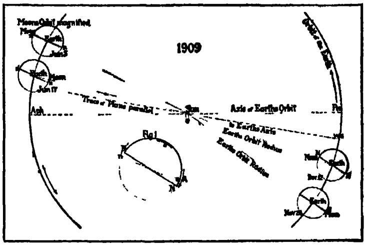
THE SOLAR AND LUNAR ECLIPSES OF 1909

BY PROF FREDERIC R. HONEY, TRINITY COLLEGE.

The intervals of time between the dates of the eclipses of the sun and moon this year, which occur alternately, illustrate the effect of the rotation of the plane of the moon's orbit in a direction contrary to her orbital motion. If this plane moved parallel to itself, there would never be more than two eclipse seasons in the year, and eclipses would occur when the earth would be at or near opposite points in its orbit, at average intervals alternately of a little more and a little less than six months. This inequality, due to the eccentricity, would evidently disappear if the line of nodes were always parallel to the axis of the orbit.

Fig. 1 illustrates the rotation of the *moon's orbit between the months of* June and December this year The lines *nn'* and *NN'* are drawn parallel respectively to the line of nodes for these months The angle included between them is about 9 degrees. The arrow *A* shows the direction of rotation of the orbit, the arrow *a*, that of the moon's motion The rotation of the line of nodes into the position *NN'* obviously will bring it into coincidence with the radius of the earth's orbit at an earlier date than the line *nn'*, which will coincide with the orbit radius when the earth has reached the opposite point in its orbit.



ROTATION OF MOON'S ORBIT BETWEEN JUNE AND DECEMBER.

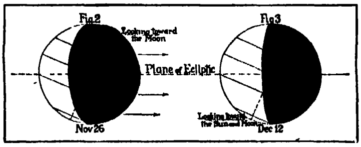
The eclipses of both the sun and moon in June occurred when the moon was in that part of her orbit which was *above* the plane of the ecliptic The eclipses in November and December will occur when the moon will be *below* that plane. In order to show this clearly, it is necessary to represent the moon's orbit on a scale very much greater than that of the earth's orbit, only a portion of which, including perihelion and aphelion, is plotted The position of the earth is shown for the dates of the eclipses on June 3 d 13 3 h. and 17 d 11 5 h, also for November 26 d 20 75 h, and December 12 d. 8 15 h, Greenwich mean time. Since the diameter of the moon's orbit is less than a half a million miles it would be correctly represented in the plot by a diameter a little less than a third of the linear eccentricity of the earth's orbit (= e) The dimension has been magnified *forty times*, in order to show the earth's and moon's orbit radii and the line of nodes clearly, which would be indistinguishable by the smaller scale It should be noted that in magnifying the moon's orbit, the relation between *these lines is not disturbed, that is*, the angles included between them are preserved In the drawing the diameter is enlarged sufficiently to show that on June 3rd, the date of the first lunar eclipse this year, when the earth's and moon's orbit radii were projected in the same line on the plane of the ecliptic, the moon was approaching the descending node *n'*, and was above the plane of the ecliptic. On June 17th, the date of the solar eclipse, the plot shows that the moon had recently passed the ascending node *n* but her distance was so far from the node and above the plane of the ecliptic, that while the eclipse was central, the moon's shadow was projected on the earth very near the north pole.

On November 26th the date of the total eclipse of the moon, the plot shows that the moon will be below the ecliptic and approaching the ascending node *N* On December 12th the date of the partial eclipse of the sun, the moon will be below the ecliptic and will have recently passed the descending node *N'* The distance below the ecliptic will be so great, that the eclipse will be visible principally in the region of the south pole.

The enlarged plot of the moon's orbit shows the position of the moon at Greenwich noon for each day from November 21st to December 18th, and also at the dates of the eclipses. On November 26th, when the moon will be near perigee *P* and very nearly a minimum distance from the earth, she will come wholly within the earth's shadow On December 12th the enlarged plot shows more clearly the great distance between the moon and the node at the time of the eclipse of the sun These plots may be compared with those printed in the SCIENTIFIC AMERICAN for May 15th, 1909 ("The Lunar and Solar Eclipses in June, 1909"). Figs. 2 and 3 are projections of the earth on a plane parallel to its axis, and perpendicular to the plane of the ecliptic. Its trace on the plane of the ecliptic drawn through the sun evidently intersects the earth's orbit at points which the earth reaches at the dates of the summer and winter solstices. In these projections less than one-half the visible hemisphere is illuminated between the autumnal equinox and the winter solstice.

The direction in which the eclipse of the moon will be seen, Fig. 2, is shown by the arrows. It will be visible at Washington, the beginning visible generally in North and South America, and northeastern Asia, the ending generally visible in North America, northwestern South America, eastern and northern Asia, and Australia.

In Fig. 3 the arrow shows the direction in which the eclipse of the sun will be seen. The limit of visibility will include a very small part of Australia New Zealand, Tasmania and the South Shetland Islands.



DIRECTION IN WHICH ECLIPSES WILL BE SEEN.

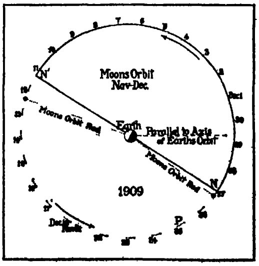
Why the Pole Shifts.

It is well established that, at least during historic times, no changes of any considerable magnitude have occurred in the latitudes of places on the earth. It has long been suspected by astronomers, however, that minute changes of latitude were taking place, but it is *only during the last quarter century that the methods* of observation and calculation have reached that degree of refinement necessary to detect these small changes.

In 1884 and 1885 Dr Küstner, astronomer at the Royal Observatory of Berlin, made a series of observations upon certain stars for the purpose of determining the constant of aberration—the maximum apparent displacement of a star due to the finite ratio between the speed of the earth in its orbit and the velocity of light. One of the quantities used in the reduction of these observations is the latitude of the place of observation. Dr. Küstner found his results to be discordant, much more so than he had good reason to believe they should be from the [illegible] precision with which the observations [illegible]. Upon investigation it was found that these discrepancies could be almost entirely explained away by assuming a change in the latitude. Dr. Küstner, [illegible] in 1888, made the bold announcement that the latitude of the Berlin Observatory had changed during the period over which his observations extended.



ENLARGED PLOT OF MOON'S ORBIT.

This announcement aroused widespread interest, and steps were immediately taken by the International Geodetic Association to test the reality of the announced variation. Through the co-operation of the observatories at Berlin, Potsdam, Prague, and Strasburg, observations for latitude were begun in 1889 and carried on continuously over a year These observations agreed in showing a minute but appreciable change in the latitude. In order to test the matter still further, an expedition was sent in 1891-2 to Honolulu, and observations for latitude were made there simultaneously with others made at the observatories just named. As Honolulu is on the opposite side of the earth from Europe, it is seen at once that if the latitude were increasing at the European observatories, a corresponding decrease should be shown at the Honolulu station. The results came out as expected, and this was generally accepted as a complete demonstration of the reality of this phenomenon.

What is the cause of this wandering of the Pole? In an article by Dr Sidney Dean Townley of Stanford University, this explanation is given.

In 1765 Euler, a famous Swiss mathematician, demonstrated, as a proposition in dynamics, that if a free rigid oblate spheroid rotates about an axis which differs slightly from the axis of figure, or shortest axis, then the axis of figure will revolve about the axis of rotation in a period the length of which will depend upon several factors He computed that, if the assumed conditions obtained for the earth, then the period of revolution of the axis of figure above the axis of rotation would be 306 days. Obviously, however, the earth is not rigid, the oceans are quite plastic and the ground itself is possessed of some elasticity Prof. Newcomb computed some years ago that, if we assume the earth as a whole to possess the rigidity of steel, then the period of revolution of the one axis about the other would be 441 days, as against 306 days found by Euler on the assumption that the earth is perfectly rigid. The actual observed period is fourteen months, or 427 days, and the *legitimate conclusion to be* drawn is that the earth as a whole is somewhat more rigid than steel—a conclusion that agrees with that derived by Lord Kelvin and others from entirely different considerations.

Now the question arises, Why does the earth not rotate upon its shortest axis? The explanation is simple. If the earth ever did rotate upon its shortest axis it could not continue to do so because of the shifting of matter upon and within the surface. Winds, rains, rivers, and ocean currents are ceaselessly transporting matter from point to point, and during the winter great masses of snow and ice accumulate in the temperate and frigid zones only to disappear again in the summer Although these effects will, to a large extent, neutralise each other, the sum total can not be other than to produce at least a theoretical lop-sidedness to the earth; and as soon as this takes place there must be a shifting of the axis of rotation. The time of revolution of the one axis about the other could be accurately computed if the exact form of the earth, the structure of the earth's interior, and its coefficient of elasticity were known.

In addition, there are other phenomena, namely, volcanoes and earthquakes, through which considerable quantities of matter may be displaced. That the amplitude of the polar motion might be affected by earthquakes was pointed out by Prof. Milne ten or fifteen years ago and a French scientist has more recently compiled a table showing the number of severe earthquakes each year and the amplitude of the polar displacement. A rough proportionality between the two seems to exist; that is, the greater number of earthquakes each year, the greater the amplitude of the polar displacement. Such results, however, are to be taken with several grains of allowance. The term "severe earthquakes" is rather indefinite and by modifying the definition quite a variety of results may be obtained from the given data. It might be pointed out that in 1906, the year of the great [illegible] in California and Chile, the amplitude of the polar displacement was small.

We have then a [illegible]

[illegible] according to the [illegible] the axis of figure must revolve [illegible] giving rise to the changes of latitude. But on account of the changes incessantly taking place in the distribution of matter upon the earth's surface, and perhaps also within the surface, the amplitude of the polar displacement, and perhaps the principal period of revolution of the one axis about the other, are changeable, the changes taking place in an undetermined way.

In connection with this explanation we should not lose sight of the fact that all the material moved through meteorological, volcanic, and seismic agencies is probably almost infinitesimal as compared with the total mass of the earth, and no one has as yet shown that the shifting masses are sufficient in magnitude to account properly for the observed annual and other unexplained components of the polar motion.—Abstracted from the Popular Science Monthly

An International Sport Exposition.

An exposition devoted to sports and games is to be held in Frankfort-on-the-Main in 1910 Frankfort is annually the scene of many sporting contests, for which reason the selection of the city for the purpose of an international exposition is certainly wise. An executive committee has been formed the first task of which was to give the organization its name, which rings imposingly "Verein Internationale Ausstellung fuer Sport und Spiel." The exposition will be divided into the following groups 1 Horses and vehicles (harness, riding and driving equipment, stables, horse breeding and care) 2. Automobiles and motor-driven vehicles. 3 Turf sports, such as gymnastics, fencing, open-air athletics (tennis, football, golf, handball, polo, cricket, gymnastic apparatus, weapons, etc.) 4 Aquatic sports (rowboats, sailboats, motor boats, swimming, and fishing) 5. Winter and Alpine sports (skates, skis, snowshoes, sleds, huts, climbing outfits) 6. Hunting (guns, sportsmen's apparatus, stuffed animals) 7 Aerial sports (free balloons, dirigible airships, flying machines, models, aeronautic instruments) 8 Tourists' exhibits, such as photographic and optical apparatus (charts, guide books, history and literature of traveling, telescopes, etc) 9 Application of sport to therapeutics (gymnastic apparatus, life-saving devices transportation of invalids) 10 Sporting outfits of all kinds 11 The artistic side of sport. 12. Toys. 13. Miscellaneous.

Award of a Medal for the Discovery of Bakelite.

At the second regular session of the New York Section of the American Chemical Society, held at the Chemists' Club, 108 West 55th Street in this city, on the evening of November 5th, Dr Leo H. Baekeland, president of the Electro-Chemical Society, was awarded and presented with the Nichols medal for his papers on "The Synthesis, Constitution, and Industrial Application of Bakelite" and "Soluble and Fusible Resinous Condensation Products of Formaldehyde and Phenol."

In accepting the medal Dr Baekeland expressed his thanks for this expression of regard for his work, and alluded feelingly to the friendly co-operation and aid he had received from the fellow members of the section He then exhibited several industrial applications of the new compound bakelite, and made an experimental comparison of the resiliency of a ball of bakelite the size of a billiard ball with an ivory billiard ball A stand three feet high was set upon the lecture table. The ivory ball was then dropped from the upper side of the stand to the table, the height of its rebound was noted, and the length of time of the rebound until it came to rest, which was six seconds, by the use of a stop watch. The ball of bakelite passing through the same height to the table rebounded at least six inches higher and came to rest in ten seconds, showing much greater resiliency than ivory

Bakelite is used very successfully in the manufacture of electro-magnet spools, and is claimed to be superior to gutta percha in that it will stand a greater degree of heat, in the event of a short circuit.

◆

The Current Supplement.

The opening article in the current SUPPLEMENT, No 1768, deals with Henry Farman's new biplane. An excellent picture of the machine with Farman seated in it is presented. The first installment of an article on bakelite, a new composition, is given by L. H Baekeland, its inventor. Samuel K. Patteson writes instructively on the measurement of humidity The relation of Charles Darwin to Mendelism is set forth by Dr. A. E. Shipley. Recent models of superheated steam locomotives are described and illustrated. An illustrated description of the fast turbine yacht "Winchester" is published. Major H. L. Hawthorne critically points out the advantages and defects of balloons and dirigibles in war. Mr. [illegible] concludes his article on the making of automobile tires. Harvey [illegible] tells how the [illegible] to the surface treatment of roads. The usual electrical, engineering, and trade notes and formulas will be found in their accustomed places.

Correspondence.

FIGHTING POWER OF THE "INFLEXIBLE."

To the Editor of the SCIENTIFIC AMERICAN

May I call the attention of your correspondent, Emerson B. Manley, whose letter appeared in your issue of October 23rd, to the fact that the "Inflexible" is not a sister ship of the "Dreadnought"? The "Inflexible," despite the number and power of her guns, is not rated as a battleship, but belongs to the cruiser class.

In an engagement between such a ship and a battleship carrying four 12-inch guns and a powerful secondary battery of 8's and 7's, it is most improbable that the ship of the "Inflexible" type would engage—and her excessive speed would give her the range decision—at such a range that her enemy's secondary battery could be effective Her preponderance in big gun power—eight 12's against four—would enable her to demolish the secondary battery before the 8-inch and 7 inch guns could get a single effective shot home.

WHY WATCH SPRINGS BREAK.

To the Editor of the SCIENTIFIC AMERICAN

Being an old subscriber to your most valuable paper, I take the liberty of writing you regarding the unusual, or I should say peculiar, action of main springs in watches. My father, an horologist of over fifty years, and I, who learned the trade from him, have had some, as we think, remarkable experiences in the main-spring line We think climate has much to do with their breakage, but if a watchmaker with sweaty hands handles a spring, there will be trouble Also one who uses gasoline or any of the similar fluids will have the same trouble.

Our trouble has been mostly in the season when electric storms prevail, or a sudden change of temperature. We always advise our customers not to put watches on a marble dresser or any cold surface, but leave them in their pocket. The temperature in the vest or other garment changes gradually, and thus does away with any sudden expansion or contraction We have been in the Mississippi Valley for many years, and our experience has been that, specially during the fall and spring seasons, during thunder storms we have more trouble with main springs. Sweaty hands do no good to a main spring Tissue paper, in our experience is the proper thing to wipe a spring with May be slightly oiled. My father has been very successful in that line of watch repairing

RAILWAY MOTOR CARS.

To the Editor of the SCIENTIFIC AMERICAN

In your last issue I notice that you are to have a special issue on the middle West. I wish you would call attention through your valuable magazine to the need of some kind of a motor car that will run on railway tracks. It should be an independent motor car, run by its own engines. There is an opening for thousands of miles of so-called interurban railways in Iowa and other middle West States, where it would not pay to build an electric railway line on account of the large expense, but if some economical and reliable form of independent motor car could be perfected, such cars could be used for passenger traffic, and small steam locomotives for freight cars and such roads would pay well The track should be built on modern lines, with easy grades and curves and independent right of way, so that trains and cars can make good time for passenger service and can also handle freight cheaply, by use of regular freight cars from the steam roads, and thus would be valuable feeders and distributers for the steam roads, where branch steam lines would hardly pay Such motor cars for passenger service should also be used on many branch steam railway lines, where better passenger service is badly needed, and where steam passenger trains are too expensive to run often enough to give good service

Motor cars of this sort to use gasoline for power have been perfected and are in use in several places but they are gradually being abandoned on account of the constantly increasing cost of gasoline It seems that little or no progress is being made in perfecting such motor cars to use alcohol or kerosene. Might not the producer-gas engines for small boats requiring less than 500 horse-power be adapted for these motor cars? In your issue of September 18th 1909, on page 191, you made mention of a very remarkable demonstration of the possibilities of producer-gas engines of this sort by Mr H L. Aldrich, using pea-anthracite, which at a cost of $4 per ton is stated to be one-tenth the cost of operation of a gasoline engine with gasoline at 15 cents a gallon, to produce equivalent power

For a long time it has seemed to me that there is an excellent opportunity for invention in the production of such an independent motor car, operated by some power other than gasoline. Some cars of this sort are in apparently successful operation which generate electric power by means of a gasoline engine, but it seems that in so roundabout a system, there must be a large waste of power

Equipped with motor cars of the sort suggested, such railways could be built much cheaper than trolley lines, and also operated much cheaper, until the business grows to a point where it would pay to change to electric power The perfecting of such a car would mean the building of many miles of new railways, and possibly the cars would also be adopted in time by the steam railways to give better local passenger service. Many good towns in Iowa are made "whistling stations" by the steam roads in their mad race for through business

Lack of better railway facilities, and lack of many miles of new railways that should have been built long ago, are factors that are holding back the development of a great deal of this middle West country

Steam railways want through business, long hauls, and great tonnage, electric railways are too expensive as yet in many places If a motor car that is light, reliable and not expensive to operate can be perfected using producer gas engines there is no question but that there is a great opportunity and opening for such a car, as above suggested

I trust that you will deem this communication as important as the number of our ancestors, for instance.

ANOTHER EVIL OF DEFORESTATION

To the Editor of the SCIENTIFIC AMERICAN

One of the recognized evils produced by the wood men who spare no tree (but leave where once the lord of the forest stood, the earth all bleak and bare) is the reduction in the yield of water power But it seems that the fact that deforestation also increases the cost of what water power you do get, has never been mentioned

Suppose that the flood level of a normal river is such as to require a 25 foot dam for power purposes. After the valley has been skinned of its foliage the flood level will be so much greater that a dam 30 feet or more in height will be necessary

As the cost of dams increases with the squares of the heights (because the higher up the thicker), the 30-foot dam will cost nearly fifty per cent more than the 25 foot and yet it will yield less power than the 25-foot would yield in the normal river because deforestation has diminished the flow of water in the dry season

The yield in the dry season is the available yield, because the larger yield at other seasons is of little value for almost all users of power want power all the year around

It is true as I showed in my article in Cassier's Magazine of September 1909 that if we would use both turbines and current motors in the same dam, high dams would not be necessary in many rivers, but this truth may be disregarded because it will probably be a hundred years before the system there mentioned will meet the right man the man who will introduce it.

SYLVESTER STEWART

Brooklyn, N Y

The Death of Theodore R. Timby

Theodore R Timby died on November 9th 1909 at Brooklyn, N Y He was chiefly known because of his claim to having invented the revolving turret of the famous Monitor" and that accordingly, he should have received the fame history accorded to John Ericsson For more than forty years he had tried to collect $500 000 from the United States for two inventions, one the revolving turret on warships and the other a device that points and fires heavy guns with electricity Other things which Timby invented, and from which he obtained both recognition and financial reward, were a floating drydock a system of coast defense, and a turbine wheel which proved especially successful

The meeting of the British Association in Winnipeg on August 25th is the third which has been held in the Dominion The first Canadian meeting took place in 1884 at Montreal, the second thirteen years later at Toronto The fact that the third was held at Winnipeg may be regarded as significant of the enormous development of the West during the past few years.

HOW LEMON OIL IS MADE.

BY FRANK N [illegible]

We all know that the flavoring extracts used in this country are of domestic manufacture and that the two principal flavors are vanilla and lemon but few have a knowledge of what actually constitutes these extracts To quote from the standards laid down by the United States Department of Agriculture a flavoring extract is a solution in ethyl alcohol of proper strength of the sapid and odorous principles derived from an aromatic plant or parts of the plant with or without its coloring matter and conforms in name to the plant used in its preparation Peach strawberry pineapple and some other flavoring extracts are always artificial it being impossible to make an acceptable extract from the fruit itself and therefore cannot be in accordance with the United States standard termed flavoring extracts However very little flavoring extract is used outside of vanilla and lemon as at least ninety five per cent of the extracts manufactured are of these two varieties The government through the Agricultural Department has delved deeply into the methods of the manufacture of flavoring extracts but the story as to how the lemon oil is made from which the extract is manufactured is the more interesting

The oil of the lemon is the essential oil secreted by cells lying near the outer surface of the rind and the world's supply of this oil comes from the island of Sicily in the Mediterranean Sea This island is the greatest lemon producing region in the world and all parts of the world receive their supply from that island The oil for making the extract is produced as a by product of the crop from the culled lemons—those which for any reason will not stand shipment

For obtaining the lemon oil there are three processes all of which are extremely crude There are two processes known as the sponge methods and one known as the machine method In the sponge methods the lemons are cut in pieces by children and women the cheapest form of labor The work is carried on with great rapidity the knife being started through the rind and the fruit cut in two and thrown into storage tubs by one motion of the arm The tubs containing the halved lemons are dumped into shallow troughs where the pulp is separated from the skins For this work older girls and women are employed and so expert do they become that in the twinkling of the eye a spoon shaped instrument is inserted between the pulp and rind and with one twisting motion the pulp is scooped cleanly from the rind and deposited in the trough The rinds are thrown into baskets to be conveyed to the spongers However before the sponging process is begun the baskets of rinds are immersed in water for four or five hours The work of extracting the oil is done entirely by men as the task is quite a laborious one These workers sit upon low stools the skins being dumped upon the floor near them and a basket for the exhausted skins set in a convenient place A small earthenware bowl is placed on the floor between the workman's knees This bowl has at one side a lip directly beneath which is a concave depression which serves to hold back the residue when the oil is poured from it Across the top of the bowl is placed a round stick about one inch in diameter notched to fit the widest part of the vessel. Across this stick is hung a flat sponge surmounted by another thicker one and finally a third, which is cup-shaped into which the lemon rind is inserted with one hand the other being used to press the sponge, the weight of the whole body being thrown into the motion The lemon skin is then turned partly over and the pressure renewed Each half rind is handled separately receiving three or four pressings It requires about two thousand of these half rinds to produce one pound of oil, the exact quantity depending upon the size ripeness and freshness of the lemons The green fruits produce more oil than the ripe A good workman can squeeze out two or three pounds of oil a day for which he receives about fifty cents This oil is worth in quantities about one dollar a pound But for making lemon extract, but a small portion is required The method of manufacture is simple The oil is dissolved in strong alcohol in the proportion of five parts oil and ninety five parts alcohol it is then filtered and bottled An idea of the small proportion of the oil required may be had when it is considered that five barrels of the oil and ninety five barrels of alcohol would make just one hundred barrels of pure lemon extract.

By the two-piece method only a small quantity of water is expressed with the oil and the process of separation is very simple, the bowl being tilted forward until the oil can be blown from the surface over its edge into another receptacle. The water and residue remaining are separated from the traces of oil by the [illegible] tissues, and [illegible] through felt bags The residue left in these bags is [illegible] for several days, when the bags are placed under a hand press and freed from the last traces of oil. What is known as the three-piece method differs from the one just described mainly in the preparation of the skins before pressing The rind of the fruit is pared off in three slices, leaving the greater part of the pulp with some little skin at the ends. This paring, as a rule, is done by boys or men, and the skins are washed and soaked as in the two-piece process. Much more pulp is left adhering to the skins in the three-piece method, and naturally more juice is mingled with the oil than by the other method The claim is made, however that oil made in this way filters more rapidly and remains clear longer

The use of machines in producing lemon oil is confined to the Province of Calabria in Italy But the oil manufactured in this way forms but a small percentage of the total product It has however a deeper color than the oil pressed out by hand and is used to deepen the color of the latter product The machine for extracting lemon oil is about as crude as the hand process The fruit fed to this machine must be of uniform size and in small quantities The lemons are placed in a receptacle between the grinding disks the lower of which is stationary while the upper one is turned by an arrangement of wooden cogs against the side flywheel The pressure exerted by the weight of the upper disk is partly compensated for by the arm at the rear which is also used to raise this part of the machine so that the fruit may be placed in position and the pulp removed A bell rings after a certain number of revolutions and the machine is stopped to remove the squeezed rinds and to reload the receptacle Indeed this machine method of oil extraction is no faster than the sponge processes followed by the inhabitants of the island of Sicily

Sand Lime Brick

According to the U S Geological Survey the sand lime brick industry is a comparatively new one in the United States having had its beginning in Michigan City Ind in 1901 Its progress was slow at first the value of the production in 1903 being only $155 040 From that time the value increased each year until 1907 when the maximum of $1 225 769 was reached In common with other building materials there was a decrease in 1908 in the production of sand lime brick to $961 226 The number of plants reporting made a rapid growth from 16 in 1903 to 94 in 1907, with a slight decrease in 1908 (to 87)

Common front, and fancy brick were manufactured from sand and lime in 1908 The average price per 1 000 for common brick was $6 63 as against $6.61 in 1907 and $6 71 in 1906 for front brick the price was $12 16, against $10 96 in 1907 and $10 42 in 1906. In 1908 common brick composed 83.87 per cent of the value of all bricks, and front brick 15 37 per cent.

Thirty States reported both in 1907 and 1908, Alabama dropping out of the list in 1908 and Montana appearing Of the individual States Michigan, as in 1907, was the leading State in 1908, [illegible] valued at $[illegible]. Florida was [illegible]

ARTILLERY FOR AIRSHIP ATTACK.

[illegible]

After having carefully studied the problem which is presented by the conditions of firing at great heights and at a large angle such as is required for use with airships, aeroplanes or balloons, the Krupp firm has brought out three general types of cannon each of which is adapted for a special use. In the first place we have the more simple type of cannon with field mounting, while a second type is constructed with a view of being placed upon a motor car For use on shipboard they design a third type which is represented in our engraving In the second and third cases the cannon is designed to be rapidly rotated in all directions by the use of a central pivot base such as is usually installed on vessels and for coast defense use On the other hand the field gun has its wheels arranged so as to turn upon pivots which allows of placing the wheels in the crosswise direction in the position here shown In order to give effective results it is found that the angle of elevation must be at least 70 degrees and the field gun is designed to reach this angle The automobile and ship cannon will however make a greater angle the maximum being for these two types as high as 75 degrees In all these cases a rapid rate of firing is given by an automatic opening and closing of the breech The caliber has been reduced as much as possible as also the weight of the projectile while the long bore gives a high initial speed to the shot and diminishes the time required to attain the mark. Owing to the lessening of the caliber greater lightness is obtained and this is of service especially in the field and the automobile types of gun

Sighting is carried out in the most efficient manner by the use of an appropriate form of sighting telescope in combination with a general finder which covers a wider range of field There is also a range-finder by which the distance is first obtained and afterward the indications are directly given so as to be able to point the gun for different heights of the airship without loss of time and thus the use of firing tables is dispensed with in all these cases

The question of the kind of shot which is best adapted for firing upon balloons or airships is of prime importance and this matter has been made the object of a number of experiments It is recognized that shrapnel will penetrate the balloon envelope but without doing much damage at least of an immediate nature seeing that the holes are closed again for the most part by the internal pressure of the gas so that the loss of gas is not a rapid one and the airship is able to reach a place of safety in the majority of cases It is found that the most effective form of projectile is a special kind of grenade which is designed to explode in the interior of the balloon and to bring about ignition of the gas The new projectile designed by the Krupp firm is intended to accomplish this and at the same time the path of the projectile from the time it leaves the gun can be followed by the use of a special smoke producer carried on the shot. By observing the trail of smoke the gunner learns whether the shot comes near the mark When the projectile leaves the gun the smoke producer has been set working by an appropriate device At night the path of the shot is still followed by the light which the smoke producer gives out. When it penetrates the envelope a very sensitive device causes the detonation of the grenade.

In the case of the field cannon which has a 6 5 centimeter bore (2 6 inches the weight of the gun itself is 775 pounds and that of the chassis 1 150 pounds making a total of 1 925 pounds for the cannon when prepared for actual service The gun can be turned about through a complete circle and it has a maximum vertical angle of 70 degrees The weight of the projectile for this type is 9 pounds The initial speed of the shot is 2 050 feet per second With the field gun it is possible to cover a maximum range of [illegible]8 [illegible]0 feet and a maximum height of 18 800 feet

Of a heavier build than the former and also of greater range is the second type of gun of 7 5 centimeter (3 inch) caliber which is designed to be mounted upon a heavy motor car as we represent it in our engraving Like the former it is provided with hydraulic recoil brake and in the present case there is used a middle pivot For elevating and lowering the gun [illegible] is used a double-toothed sector which is driven by pinion and crank A special arrangement is used for the rotation by which a slow movement is obtained but a quick rotation may also be given by a more rapid mechanism when it is needed to turn the gun rapidly into any desired position It is to be noted that owing to the high speed at which the airships move such quick movements are one of the features which need to be especially designed in the case of guns for balloon firing The weight of the gun itself or 990 pounds combined with the weight of the support 1 550 pounds gives a total weight of [illegible]540 pounds for this type of gun We have here the maximum angle which is reached in the Krupp cannon or 75 degrees The weight of the projectile is 12 pounds and the initial speed [illegible]060 feet per second The maximum range is about 30 000 feet and the greatest height about 20 000 feet As regards the automobile car which is designed to take the present cannon its total weight (exclusive of the gun) is 3 ½ tons and it has an average speed of 30 miles an hour

Owing to the fact that both axles are driving axles with the use of the 50-horse power motor the automobile car is able to travel over very difficult ground and it easily mounts very steep grades Under the front seat is a roomy chest which holds a good supply of tools and extra fittings and special attention has been given to this point so that the car will not easily become disabled To make the platform of the car as steady as possible during the firing the platform

(Concluded on page 383.)

The 4 2-inch Krupp gun for aeronautic attack, on a naval mount

Field gun for airship attack.

Destruction of a captive balloon by a special form of incendiary grenade.

The 3-inch 12-pounder Krupp field piece for airship attack The weapon can be brought to a maximum elevation of 75 degrees The motor car on which it is mounted is of 50 horse-power and has an average speed of 30 miles an hour

The projectile emits a train of smoke which marks the path of its flight

ARTILLERY FOR AIRSHIP ATTACK.

WIRELESS COMMUNICATION WITH BALLOONS.

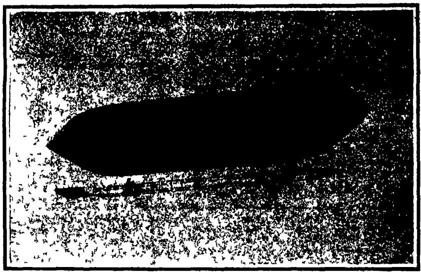
On May 13th, 1908, an ascension was made with the United States Army Signal Corps balloon No. 10 with Lieut.-Col F P Lahm, Major E. Russel, and Capt. E S Wallace as passengers. Major Russel assisted by Capt F S Wallace made some wireless telegraph experiments in this connection.

The basket of the balloon, which is about five feet long four feet wide, and three feet high, was surrounded on three sides by light galvanized wire netting about two and a half feet wide the surface being about thirty square feet When the balloon had ascended to a height of about one thousand feet, a flexible phosphor bronze wire three hundred feet long, such as is used in our army was paid out from the net of the basket not occupied by the wire netting The wireless receiving set consisted of a tuning device and small condenser similar to that used in the field wireless set connected with a silicon detector A Sullivan telephone receiver was used

The Washington navy yard station and the Annapolis station agreed to begin sending signals every fifteen minutes for five minutes each The Washington station began at 1 45 and the Annapolis station at 2 30 o'clock This sending was to be kept up until 3 30 o'clock Signals were immediately picked up from the Washington station although not very clearly, and the reception of signals continued until the balloon was about six miles away, when the Washington station could no longer be heard It was learned that the Washington station was being overhauled, and that only one of their small sets was used Signals from the Annapolis station were picked up easily as soon as the sending began, these signals coming in so loudly and clearly that it would seem as if the excellence of this means of receiving would be all but equal to that of the land station During each of the sending periods after this until 3 30 o'clock the Annapolis signals came in clearly the distance from that station varying about twenty miles at the beginning to ten miles at the close No disturbance from atmospheric electricity was apparent although the vertical antenna was several times left disconnected for some little period, in order to see if any spark could be obtained between it and the netting. No spark could be detected

It is believed by the army officers who made the experiments that this extension of the use of wireless telegraphy may prove of considerable value in extending the usefulness of an aerial reconnaissance. It may be regarded as certain that at least over distances no greater than were worked at this time, a sending set could have been utilized It will be necessary, of course to provide some means of masking all of the apparatus which might produce hot sparks, and it is probable that a special means of preventing the gas from pouring from above should also be provided

The photographs herewith presented show a sending and receiving outfit that has been prepared for the War Department for use on a balloon, but there is no record describing this apparatus or describing any contemplated use thereof Since the apparatus was designed for aeronautic purposes it seems not unlikely that it may be used with the Baldwin dirigible.



U. S Army dirigible No. 1 (Baldwin type) with which wireless experiments may possibly be conducted.

Detail view of the aerial wireless set. Note the masked spark gap in the upper right-hand corner of the frame.

The wireless set employed by the Signal Corps for aeronautic use. The total weight is about 70 lbs. An 8-volt, 20-lb. accumulator supplies the current.

WIRELESS COMMUNICATION WITH BALLOONS.

Aeroplane Flights in America.

The efforts of the numerous experimenters in the United States and Canada are beginning to show results in the form of short flights by a number of embryo aviators just at the time when public interest in flying machines is becoming sufficiently great to cause the organizing of aviation meetings with liberal prizes, such as have been held in Italy, Germany, and England recently with the Rheims meeting in France as a model. The first such meeting in America to have more than one aeroplane make flights occurred last week at the Latonia race track at Cincinnati, Ohio. Besides flights by Glenn H. Curtiss, Charles F Willard also made a number of successful flights with the biplane of the Aeronautic Society, which is the first aeroplane Mr Curtiss built for sale. When Mr Curtiss damaged his machine by hitting a wagon in alighting, the spectators were not obliged to leave disappointed, since Willard made some excellent flights. Roy Knabenshue, Lincoln Beachy, and Cromwell Dixon, the 17-year-old aeronaut, all made excellent flights in their dirigibles, and the three-day meet was a decided success.

Encouraged by the success of Mr F Raiche in getting his small biplane off the ground at Morris Park some time ago, a number of other members of the Aeronautic Society have been actively engaged in completing their machines. The second biplane to make several short flights there was that of P Brauner and A J Smith In the morning of October 31st Mr Brauner flew about 350 feet at a height of 8 feet, and in the afternoon Dr Green made a flight of some 250 feet. The following day, after getting off the ground once, Mr Brauner, in a second attempt, sent the machine aloft too suddenly, with the result that it lost headway, dropped backward to the ground, and was smashed The aviator pitched forward but was not hurt. Using the same motor—a 25-horse-power A. & B. 4-cylinder water-cooled engine of 260 pounds weight—upon his biplane, Dr William C. Green got off the ground and made six flights of from 30 to 100 feet in length at Morris Park on the 12th instant. The last flight was made at dusk, and a wheel was broken in alighting Both of these biplanes resemble the Curtiss in design, having balancing planes and a single propeller on the engine shaft back of the main planes. They are both larger machines than the Curtiss [illegible] plane, however, [illegible]

Another aeroplanist who has [illegible] and made flights of several hundred feet [illegible] Frank Van Anden, of Islip, L. I. Mr. Van [illegible] plane is a very light machine, weighing [illegible] with a 15-horse-power motor but little more than [illegible] pounds.

At the Petawawa military camp in Canada, J. A. D. McCurdy also made a number of excellent flights recently with his new "Baddeck No. 2" biplane. This new machine, which was constructed after the "No. 1" was demolished in an accident, has shown excellent speed and stability. It is fitted with a relatively heavy 4-cylinder water-cooled motor having a single propeller on its crankshaft. In general design it is like Curtiss's, being, like his, the outcome of the experiments of the Aerial Experiment Association. Mr. McCurdy had hoped to take his machine to England and fly there for the $5,000 prize of the Daily Mail offered for the first mile flight in a circle by a British-built aeroplane piloted by a British aviator Capt. Cody, the American who has been experimenting in aeronautics for some time past for the English army, recently became naturalized so as to compete for this prize with his aeroplane. But both aviators have lost this opportunity, since Mr. J C. Moore-Brabazon, a well-known English sportsman, has lately won the prize with a machine resembling the Wright, but having peculiar balancing planes between the main planes at their ends instead of warping the latter.

◆

Gasoline vs. Alcohol.

A gallon of denatured alcohol can be made to do the same amount of work in an engine as a gallon of gasoline; moreover, the alcohol does not produce smoke and is less liable to yield obnoxious odors, but the lower price of gasoline makes it the cheaper fuel. These conclusions, based on the results of 2,000 comparative tests of the two substances as engine fuels, are given in Bulletin 392 of the United States Geological Survey R. M. Strong, the author of the bulletin, briefly describes the tests but discusses the more important results at some length. The tests formed part of the investigation of fuels now being carried on by the Survey To determine the relative efficiency and economy of gasoline it was compared with denatured alcohol. In this comparison not only the heating values of the two fuels but their adaptability to engine use and the effects of variations in fuel quality and in the principal operating conditions—such as load, fuel supply, and time of ignition—were carefully studied. Tests were made with gasoline and alcohol in the same engine and repeated in other engines of approximately the same size (10 and 15 horse-power) and the same piston speed, with different degrees of compression, different methods of governing, and different [illegible].

If most Americans were asked which is the highest mountain in the United States, they [illegible] answer Mount Rainier. As a matter of [illegible] belongs to Mount Whitney, which [illegible] ter in height by less than 200 feet. [illegible] Mount Rainier is 14,363 feet above [illegible] that of Mount Whitney, by [illegible] feet above mean sea level.

[illegible] LABORATORIES.

[illegible]

[illegible] the whole of the Sudan [illegible] world, being under [illegible] Mahdism. To-day it is a country of increasing prosperity, and at the ancient capital of the Dervishes has been erected a magnificent pile of educational buildings, the Khartum College, a portion of which comprises an extensive and elaborately equipped tropical research laboratory. When the country was finally subdued, it was realised that the peculiar conditions prevailing, both climatic and geographical, rendered the territory a difficult one for the residence of the white man. It was the home of innumerable and mysterious diseases and infectious maladies, which rendered it untenable to the white man, and were also destructive among the ranks of the natives. Moreover, these maladies were peculiarly endemic to the country, and it was realised that the only possible method of reclaiming it for civilisation was the investigation and solving of these problems upon the spot, by the most up-to-date scientific methods possible.

Scarcely had the last shots in the campaign been fired, when a movement was started for the foundation of an educational college on the site of the Mahdi's stronghold. Here it was decided to study the questions upon a small scale at first. Owing to the generous munificence of a well-known Englishman, Mr Henry S. Wellcome, however, it was found possible to establish an extensive institution for tropical research. The donor, in connection with his gift to the Sudanese government, offered to equip the laboratories with all the latest appliances that might be desired, so that the investigations could be carried out upon the most comprehensive lines. These laboratories are unique, inasmuch as they are the only ones of their character upon the African continent, which is unanimously held to be the greatest seat of all those peculiar natural conditions inimical to the white man which have appreciably retarded the development of the country in the past. But through the efforts of this institution invaluable work has been accomplished in reclaiming the northern part of the country, which, in conjunction with that of the Liverpool and London Tropical Schools of Medicine, has assisted in the hygienic betterment of the continent at large.

The work of the Wellcome Tropical Research Laboratories is broadly divided into six ramifications, as follows: (1) The promotion of technical education, (2) the bacteriological and physiological study of tropical disorders, more especially the infectious diseases of both man and beast peculiar to the Sudan, and to extend assistance to the officers of health and to the clinics of the civil and military hospitals, (3) to assist experimental investigations in poisoning cases, by the detection and experimental determination of toxic agents, particularly the obscure potent substances employed by the natives; (4) chemical and bacteriological tests in connection with water, food-stuffs, and such sanitary matters as may be found desirable, (5) the promotion of the study of disorders and pests which attack food and textile producing and other economic plant life in the Sudan, (6) to undertake the testing and assaying of agricultural, mineral, and other substances of practical interest in the industrial development of the Sudan

The work upon these diverse subjects is under the direction of Dr Andrew Balfour, B Sc D P H F.R. C P, and he is gladly assisted by the various other departments of the government which are interested in one or more of the avowed objects of the Institution such as the Egyptian Army Medical and Veterinary services, indeed, the co-operation of outside workers in the same field is much appreciated and fostered so that there may be an indisputable conclusiveness concerning the results achieved Within the first year of its foundation the laboratories became fully occupied in all their departments, and then Dr Andrew Balfour gradually and carefully selected the best fields of work, and concentrated the attention of his staff thereon Chemistry and entomology have received almost as much attention as tropical medicine, and recently the work of the Institution has been extended to the sciences of ethnology, ethnography, and anthropology

Tropical medicine comprises researches in the trypanosomiasis of animals, chiefly cattle and camels—fortunately the dreaded scourge of sleeping sickness among humans has not extended to the Sudan. Piroplasmosis, spirochætosis of Sudan fowls, and studies of the many fell diseases such as kala-azar mycetoma, and dengue fever which cripple human life in the tropics constitute the most prominent of the purely pathological and bacteriological work Then again the sanitary organization of Khartum and Omdurman has been taken in hand involving the destruction of mosquitoes and the introduction of sanitary laws and a conservancy service. Dr Balfour the director is the medical officer of health of the towns and with the adequate laboratory resources at his disposal has been able to revolutionize completely the conditions of life in a few years, and has practically exterminated malaria at Khartum

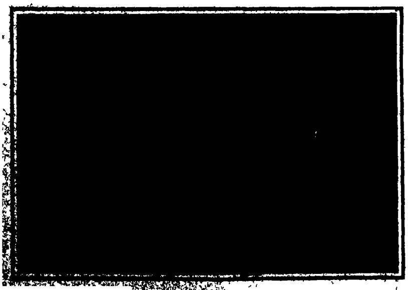
The headquarters of the laboratories are at the Gordon College, and here within a period of seven years innumerable experiments and investigations were carried to a successful issue and a mass of unique information collected which is of inestimable value in connection with the subjects treated It was found however that the conditions under which the researches were made were not quite perfect, on account of the possibility of change in or damage to bacteriological and other specimens in their transmission from remote districts to Khartum It was therefore decided to carry the war into the enemy's camp and to carry out the investigations on the spot under conditions very similar to those at the Gordon College For this purpose a floating laboratory was established and the work accomplished therewith has been of far reaching value The southern Sudan is a country criss-crossed by waterways on the banks of which are clustered native villages wherein all manner of rare and interesting pathological conditions are to be found Flies and mosquitoes abound the birds reptiles and fish harbor strange parasites men die from curious diseases and there is a vast field for the study of tropical medicine Before the days of the floating laboratory, material occasionally reached Khartum from these distant territories but too often it was in a badly damaged condition Blood slides were dirty and spoiled insects broken and notes incomplete On the whole it was recognized that the proper study of conditions must be conducted on the spot and then many valuable data could be gathered

The floating laboratory is a commodious vessel well adapted to service upon the waters of the South The main working room is completely mosquito proof and is adequately fitted out for proto-zoological and entomological work Its maiden voyage was carried out

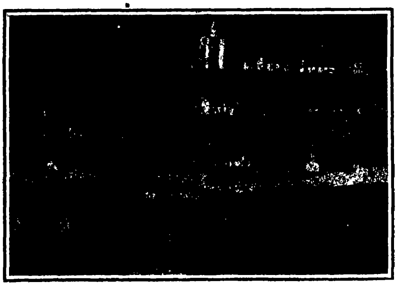
(Continued on page 381)

The floating laboratory on the Nile, auxiliary to the Wellcome Research Laboratories.

Part of bacteriological section of floating laboratory.



[illegible] room.



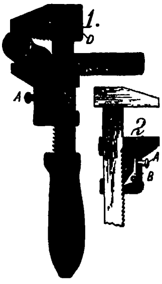
General chemical laboratory.

THE WELLCOME TROPICAL RESEARCH LABORATORIES AT KHARTUM

Patent Department

COMBINED PIPE WRENCH AND MONKEY WRENCH

The wrench illustrated herewith differs materially from the ordinary in the fact that the usual screw mechanism is entirely dispensed with and the jaws may be instantly opened or closed to any desired extent The wrench is also provided with a removable jaw piece which may be quickly applied to adapt it for use in gripping pipe or round work Fig 1 illustrates the wrench with the pipe gripping attachment applied thereon while Fig 2 shows the wrench adapted for ordinary use In this view the lower jaw is cut away to show the interior details It will be observed that the ratchet mechanism with which this wrench is equipped in place of the screw mechanism is controlled by a button *A* that projects from the forward face of the lower jaw When the button *A* is depressed the dog *B* is disengaged from the ratchet teeth permitting the jaw to be moved downward on the shank of the wrench A spring *C* serves to hold the dog in engagement with the ratchet teeth when the button *A* is released It is not necessary to operate the button *A* when closing the jaws on a piece of work but merely when it is desired to open them The pipe gripping device consists of a slotted member which may be fitted over the shank of the tool and is provided with inwardly inclined teeth as shown in the illustration The inventor of this improved wrench is Mr Charles Waller of Hamilton Wash

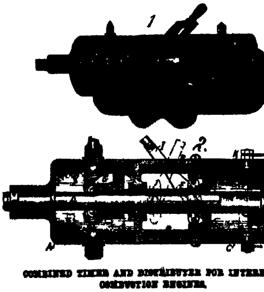


COMBINED PIPE WRENCH AND MONKEY WRENCH

◆

COMBINED TIMER AND DISTRIBUTER FOR INTERNAL COMBUSTION ENGINES

The speed of an internal combustion engine is commonly regulated by varying the time of the spark with respect to the position of the piston In the case of a multiple-cylinder engine the casing of the timing device carries a number of terminals which contact in succession with an inner rotatable member and the casing is mounted to oscillate for a limited distance in order to vary the time of the spark as above referred to A disadvantage of this system is the fact that the casing cannot be held rigid and the time of the spark cannot be accurately controlled when the engine is operated at high speed Furthermore the oscillation of the cylinder casing and the rattle and jar due to the fact that it is mounted on a single short bearing are apt in time to break away the connecting wires In the timer here illustrated the casing is fixed and the timing is accomplished by a sliding sleeve mounted on a long bearing As shown in the accompanying engraving the device comprises a casing formed of three separate sections The section *A* contains the timing mechanism, the insulated section *C* a distributer, while section *B* serves to connect the other two sections and support the controlling lever A shaft *D* runs through the two sections and is geared to the engine shaft. Mounted on the shaft *D* is a sleeve *E* A pin *F* in the shaft engages the slot in the sleeve *E* which serves to couple the sleeve to the shaft *E* and yet permit the former to slide on the latter Mounted on the sleeve *E* in the timer section is a drum which carries a spiral metal strip *G* adapted to come in contact with a series of spring pressed balls mounted in but insulated from the casing As the shaft *D* revolves it will be observed that contact is successively made with the balls *H* which control the primary winding of the coil and that by sliding the contact strip *G* along the shaft *D* the time of the contact with respect to the position of the pistons will be varied The contact strip *G* may be moved along the shaft *D* by means of a lever *I* The opposite end of the sleeve *E* carries an insulating block in which a spiral contact strip *J* of the same pitch as the strip *G* is fitted The strip *J* is adapted to make contact with buttons *K* which correspond in position with the terminals *H* and are connected to the spark plugs A metal sleeve is fitted in the insulating block in contact with the strip *J* and this is adapted to receive a metal rod *L* which bears against a plate connected with the terminal *M* By this means electrical connection is always maintained between the strip *J* and terminal *M* no matter what position the sleeve *E* may occupy along the shaft *D* This arrangement is particularly adapted for use on low speed marine engines where a single coil suffices for all cylinders For high speed automobile engines a separate coil is required for each cylinder and hence the distributer can be dispensed with The inventor of the combined timer and distributer is Mr G T Brown of 225 West 80th Street New York city

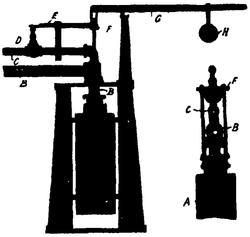


COMBINED TIMER AND DISTRIBUTER FOR INTERNAL-COMBUSTION ENGINES

◆

AN IMPROVED STEAM TRAP

Pictured in the accompanying engraving is an improved steam trap which is of simple and durable construction and arranged to discharge the water of condensation periodically as required The apparatus comprises a closed vessel *A* into the top of which the steam supply pipe *B* opens Passing through the steam supply pipe and reaching to within a short distance of the bottom of the vessel *A* is the water discharge pipe *C* The vessel *A* is adapted to slide vertically on the pipe *B* and is provided with rollers that engage guide rails at opposite sides The steam supply pipe *L* is connected with the apparatus on which the steam trap is to be used so that the water of condensation accumulates in the vessel *A* The water discharge pipe *C* is provided at *D* with a valve A lever *E* presses against the valve stem at one end while the opposite end engages a cross piece *F* attached to the vessel *A* The cross piece is in turn connected by a link to a lever *G* which carries a weight *H* that may be adjusted along its length The weight *H* may be adjusted to lift the arm *E* so that it depresses the valve stem and keeps the valve *D* closed As the water of condensation accumulates in the vessel *A* it overbalances the weight *H* drawing down the cross piece *F* and with it the lever *E* and thus releasing the valve stem which springs up under tension of a small spiral spring The steam pressure in the upper part of the vessel *A* then forces out the water of condensation through the discharge tube *C* As soon as the water is discharged, the weight *H* lifts up the vessel *A* to its normal position The weight is so adjusted that it will act before all the water in the vessel is discharged, and will leave enough water in the vessel to seal the bottom of the discharge tube *C* and prevent steam from escaping therethrough. The inventor of this improved steam trap is Mr M J Bayle, 315 49th Street, Brooklyn, N Y.

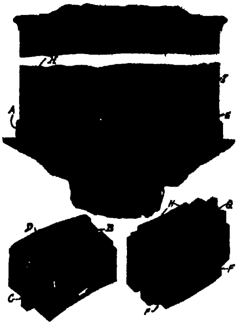


AN IMPROVED STEAM TRAP

[illegible]

A NEW GRAIN BIN CONSTRUCTION

The grain bin illustrated in the accompanying engraving is designed to provide a dry and well-ventilated structure While the construction is such that it may be easily and quickly built, it will withstand great pressure from within The floor of the bin preferably slopes downward toward the center, leading to a chute that extends to a horizontal passage below, in which is mounted an endless belt carrier The walls floor and roof of the bin are preferably constructed of blocks or tiles of fireproof construction The first course of blocks of which the wall is formed are made as indicated at *A* Each block is provided with a recess at one side and a tongue at the other so that the blocks may be successively rabbeted together It will be observed that the block *A* is provided at its outer upper edge with a flange *D* which has a lug projecting inwardly therefrom The next course of blocks which are of the form indicated at *E* are provided with recesses *F* which fit over these lugs on the flanges *D* It will be understood that each course of blocks breaks joints with the course below it The blocks *E* are provided with grooves *G* adapted to receive metallic bands which are shown in section at *I* Each block *E* is provided with a pair of vertical passages *H* which are adapted to register with similar passages in the successive courses so as to form continuous passages from top to bottom of the bin The blocks in the intermediate courses of the wall are somewhat different in form from the ones shown at *I* but it is sufficient to state that they are provided with projecting lugs that enter recesses on adjacent blocks so as to form an interlocking construction The uppermost course of blocks differs from the others in having apertures *J* which provide communication between the interior of the bin and the vertical passages These apertures are above the grain line and afford ventilation of the walls The inventor of this grain bin construction is Mr Thomas Dougherty 624 18th Avenue South Minneapolis Minn.

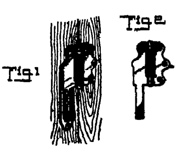


A NEW GRAIN BIN CONSTRUCTION

◆

ODDITIES IN INVENTION

Detachable Hinge.—One of the bugbears of the man who has to do his own odd jobs around the house is the putting on and taking off of screen doors particularly if provided with spring hinges It is quite a difficult matter to apply the hinge without the help of an assistant holding the screen door The invention illustrated herewith aims to overcome this difficulty by making the hinge detachable A socket piece is permanently fastened to the door jamb and the spring hinge may be fitted into this socket piece or removed at a moment's notice.



DETACHABLE HINGE.

◆

Universal Cement.—4 parts alabaster plaster and 1 part of finely pulverized gum arabic mixed with a cold saturated borax solution into a thick paste, make an unequaled all-around cement for stone, glass, bone, horn, porcelain and wood, which becomes hard as marble and possesses the agreeable quality of not solidifying immediately after mixing, but only after 24 to 36 hours.

[illegible] PATENTED INVENTIONS

Pertaining to Apparel.

SUBSTITUTE BUTTONHOLE ATTACHMENT.—F [illegible], Denver, Colo. This attachment serves as an inexpensive substitute for frayed and worn-out buttonholes and may be quickly applied and detached without the use of any device other than the hands, and when applied presents a neat appearance and does not interfere with the flexibility of the surrounding material.

RECEPTACLE FOR BABY-CLOTHS.—C. [illegible], New York, N. Y. This receptacle is adapted to be set within the bowl of a water closet during the cleansing manipulation of the cloths and to retain no water when lifted therefrom. It is provided with a plug or stopper adapted to hold the water of the flushing system in the bowl.

Electrical Devices.

HAIR-DRYING APPARATUS.—W A Sozas, New York, N Y The invention is more especially designed for use in hairdressing establishments, barber shops and other places, and is arranged to insure drying of the hair by heated air and under the invigorating influence of artificial light, by the use of an electrically driven fan arranged in the rear of a cluster of electric lamps contained in a hood open at the front for the passage of the heated air and the rays of light.

Of Interest to Farmers.

MILK PASTEURIZER AND FILTER.—C C Stambaugh, New York, N Y In the present patent the invention has in view a simple apparatus for use in the pasteurization and filtration of milk, the pasteurizing and filtering being successively and continuously performed by passing the milk through a pail or vessel having the inventor's improvements.

Of General Interest.

PACKAGE-TIE.—H J Lee and E. F Gray, Scranton, Pa The purpose here is to provide details of construction for a package tie, which are simple practical, very convenient to tie or release a package, and that particularly well adapt the improvement for binding together a number of letters or documents in a compact package that may require separation quickly

SHEET-METAL TUBING—W P Lawrence, Colorado Springs, Colo This improvement has reference more particularly to a construction of tubing for use in the frames of window sashes, window screens or for the uprights or transverse members of metal furniture, or for paneling or any other similar structure in which it may be desired to employ sheet metal tubing.

KNOCKDOWN BOX—W L. Howland, Cedar Rapids, Iowa This hollow box frame is open at the top and bottom close around the inner sides of which is disposed a continuous piece of material projecting beyond the top and bottom of the frame and having its projecting portions cut and bent down and against the top and bottom of the frame so that when the top and bottom members are secured, the continuous piece of material will be held close to the inner sides of the frame, while it may be readily removed by removing the top and bottom members.

HAND MIXING RECEPTACLE.—A. Hallenberg, Fargo, N D. This inventor furnishes a receptacle for materials wherein the same may be mixed by compression of the walls of the receptacle He provides a receptacle to receive materials to be mixed, provided with finger holds to protect the fingers, and to provide holding means for the receptacle.

MEANS FOR HANGING DOORS SCREENS, ETC.—T Gill, Follansbee, W Va. The means consists in the main of a post or column of a length nearly equal to the height of the door opening or casing and provided with a suitable adjusting device for extending its length until it clamps at its ends against the door casing with sufficient force to retain it in place, the door being hinge-connected to this post in the usual manner of connecting it directly to a door casing.

BUTTER AND LARD CUTTER.—C. H. Carlson, Iron Mountain, Mich. The aim in this instance is to provide a device especially adapted to cut out and remove a shaped pat of butter or lard from a firkin or other receptacle, and which is provided with means for ejecting the pat from the device without the necessity of touching it with the hands or any tool.

Hardware.

BENCH-STOP.—M. R. [illegible], Ellis, Kan. This invention relates to stops, and more particularly such as are adapted to be used on carpenters' benches for holding one end of a board firmly against the apron of a bench while the opposite end of the board is clamped in a vise. It constitutes an improvement on the device shown and described in a U. S. patent formerly granted to Mr. [illegible].

HOSE-COUPLING.—W. F. [illegible], Chillicothe, Ohio. In using this invention, the head piece is introduced in the terminal of the [illegible] member having [illegible] and it is rotated in the terminal until the pleats of the T-shaped members are in alinement with the slots that separate the pairs of lugs, when the head piece is pulled outwardly until the T-shaped members interlock with the inner fixed lugs. In this position the head piece protrudes through an opening in the rubber cup.

Household Utilities.

CLOTHES-LINE HANGER.—C C. Lovejoy, New York, N Y The device may be conveniently attached, and will operate to support the line in such a way that the end of the line may be brought into the room to enable the clothes to be hung thereupon, and the device may be readily folded up out of the way when not in use

CLOTHES-LINE TIGHTENER.—R. C Schubner and L. Marek, Union Hill, N J This invention pertains to clothes line tighteners, and the object of the inventors is to produce a device which can be readily applied to a clothes line, which will enable the slack of the line to be taken up and which will maintain the line under tension

Machines and Mechanical Devices.

DEVELOPING MACHINE FOR PHOTOGRAPHIC FILMS.—Elizabeth A Taylor, Steilacoom, Wash This invention consists of a plurality of cylinders of different diameters disposed one within the other, there being slots in the cylinders, and projecting therein which engage each other so that when one cylinder is rotated a predetermined distance the projection thereon will engage the one on a neighboring cylinder to rotate it In use the end of the film is secured to one of the cylinders and as they are rotated the film is wound around them, the film passing through the slots from one cylinder to another

Musical Devices.

REED-ORGAN—L. A. McCord, Laurens, S. C It is sought in this invention to provide an organ attachment which can be applied to any of the ordinary reed organs and will permit the playing of the organ by an automatic or self player such for instance as those using a certain perforated paper strip or sheet, and which self playing attachment may be adjusted out of the way so the organ may be played in the usual manner

ADJUSTABLE PIANO-PEDAL CONNECTION—H Meyer, New York, N Y The intention here is to provide an adjustable piano pedal connection arranged to insure accurate working of the hammer rest rail, the damper rail and the muffler as desired. The connecting bar is adjustably secured to a flat spring, which forms the fulcrum for the bar and is attached to a base secured to the bottom of the piano frame

Railways and Their Accessories.

RAILROAD-TIE—J W Snedden, Falls Creek Pa Disclosed in this patent is a tie the sides of which are connected below the top by a web, the upper edges of the sides having inwardly projecting flanges between which the movable member of the rail fastening means coact with fixed rail retainers at the opposite side of the rail The tie is hollow and between the walls either a filling of concrete or a block of wood is adapted to be received

BLOCK-SIGNAL SYSTEM—J D Nix, Ferriday La An object of this inventor is to provide a mechanism which is located on the engine and forms part of the mechanism thereof which may be automatically operated by an electric current from a generator carried on another engine which is in the same block The generators for furnishing the current may be either dynamos or batteries.

FLAG OR SIGNAL.—G W Dallimore, Pocatello, Idaho The object here is to produce a flag for use on railways having a pole or staff within which the curtain or body of the flag may be received when the signal is not being displayed, and further, to provide a simple construction enabling a flag to be extended or withdrawn from view

CAR-FENDER.—G A. Estlee, Standish, Mich In this fender, a catching and supporting means prevents injury to a person with whom the fender has forcible contact, and the purpose of the invention is to provide for a fender effective in service, and which may be placed on street or other cars for service without requiring changes in the construction of the cars.

LOCK VALVE.—T M. Swank, Louisville, Ky This valve is for use in connection with the train pipe of an air brake system, which has locking mechanism serving to prevent unauthorized and malicious tampering with the valve, which also prevents accidental closing of the valve when open, and which will not cause unnecessary delay in certain operations such as in switching or coupling cars.

AUTOMATIC TRACK INSPECTOR.—T Ellis, Tacoma; G H Purvis, Seattle, and J S. Crusoe, Raymond, Wash. The invention relates to automatic track inspectors, that is, to mechanism for indicating the condition of a railway track. More particularly stated it comprises various improvements, whereby the general efficiency of such mechanism is greatly increased, and the operations rendered more [illegible].

Pertaining to Recreation.

COMBINED CREEL AND KIT.—H. W Wakefield and C. F Haster, Seattle, Wash. The improvement is in anglers creels, the purpose of which is the provision of a kit in connection with the creel or basket for the storing of hooks, lines, leaders and other fishing paraphernalia, in order that the same may be at all times readily accessible and thus facilitate the replacing of lost hooks, etc.

GAME.—H. E. Hire, Mark Center, Ohio. Mr Hire's invention relates to games, and the object is to provide a game which has many of the features of the game of base ball and is especially devised to assist in the training of pitchers for the outdoor game of base ball, and to test their skill at the outdoor game

TOY CANNON.—W H. Cornford, Mornington, Victoria, Australia. This application is in part a division of the application formerly filed by Mr Cornford for Letters Patent on a military game or toy and the present invention relates to a toy cannon or gun of special construction adapted to be used in connection with the said game It provides for rapid firing of pellets, retaining them in position till fired, automatically readjusting them if displaced, and means for elevating and depressing the cannon.

Pertaining to Vehicles.

INFLATING DEVICE FOR TIRES.—E. Haynes, Bisbee Ariz Ter This invention is particularly useful in connection with pneumatic tires such as are used on motor vehicles and the like The aim is to provide an efficient device for tires, which is automatic in operation and which obviates the necessity for manually or otherwise extraneously inflating a tire

VEHICLE-TIRE.—C F Fisk, Allentown N J The invention consists of a rim of two sections bolted or otherwise detachably secured to the felly and having relatively deep outwardly-extending flanges, with a shoe rim at the outside of each flange a tire having resilient ribs in engagement only with the inner faces of the flanges and the tire and ribs otherwise disengaged from the rim, a shoe extending around the tread of the tire having its edges located in the shoe rims, and clamping rings securing the shoe to the shoe rims.

DRIVING-GEAR FOR AUTOMOBILES.—E G Whitacre, Wellsville Ohio This invention relates more particularly to the mounting for the driving engines used in automobiles. The style of the engine may vary but any form wherein the motive power is a gas under pressure will serve. It might be used in internal combustion engines provided any of the well known relief valves were used in conjunction with one or the other of the engines, which would be operated automatically as the automobile is driven in a curved path The valve would lessen the power stroke on the engine on the inner side of the curved path being followed by the automobile.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each Please state the name of the patentee, title of the invention and date of this paper

Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th or will be sent by mail on request.

(12136) A. R. S. says 1 Why when the moon is growing can one see a bright outline of that satellite, while the inner portion of the circle appears dark? A When the moon is within two or three days of new the earth reflects light enough from the sun to make the dark portion of the moon visible The earth at that time is full as seen from the moon This is called seeing 'the old moon in the new moon's arms.' The light is called 'earthshine' It is described in the astronomies, such as Todd's 'New Astronomy' which we send for $1.50 See page 225 2. Why do moon and sun appear to be much larger when rising and setting? A The sun and moon seem larger near the horizon by an optical illusion due to contrast. With an instrument they do not measure any larger near the horizon The sky itself is affected in the same way Stars seem farther apart 3 How can I locate the following planets Mercury Mars, Jupiter Neptune Venus? A. The position of the planets is given each month in our article 'The Heavens in September" etc The proper thing to do is to become a subscriber to the Scientific American and have the instruction given in the paper Neptune cannot be seen excepting with a good telescope The rest you name may be seen with the unaided eye. Mars is now very bright in the night sky 4 What size wire will be necessary to wind an ordinary telephone generator for ten volts? How many turns will be required? A A telephone generator is wound with wire from No 30 to No. 35 and from 75 ohms to 550 ohms. From this you will see that we cannot tell you what to use. If you would make a generator to work with others, you would better copy one of the others.

(12137) C L. L. says Two horses are attached to opposite ends of a rope and are pulling against each other Both horses are capable of pulling 200 pounds apiece. Is there more strain on the rope with the horses pulling against each other than if one end of the rope is attached to an immovable stake and only one horse pulling it? A The pull upon the rope with a horse pulling 200 pounds at each end is 200 pounds. One horse is but a post for the other to pull against and a post can as well be used as a second horse This anyone can prove by having two persons pull against each other on a spring balance and then letting one person pull with the balance fastened to a hook on the wall or to a hitching post in the yard If the balance will indicate all that a person can pull the experiment will be identical with the one you propose

(12138) F S says Some time ago we wrote to an electrical supply house asking them whether the numbers in the Brown & Sharp wire tables followed any regular law and were told that they did not We are of the impression that the people we wrote to concerning this question must be mistaken, and are writing you, and would like to have you either confirm or deny their statement A The sizes of wires by Brown & Sharp s, or as it is better termed the American wire gage are not determined by any formula but are a growth. However the sizes are such that a wire three sizes larger will have a sectional area about double that of a given wire This is only an approximation It is very convenient in electrical work. See our article, 'How to Remember the Wire Table' in Supplement No 1 690 price ten cents.

(12139) W B H says 1 Why is a magneto used to make the spark for a gasoline engine in preference to a small dynamo? A The field of a magneto is always ready for use and does not require to build up its magnetism as a dynamo does. 2 Why are the permanent magnets of a magneto divided up into several instead of one large one? A. A compound magnet made from several thin magnets is much stronger than a single magnet of one thick piece of steel

Legal Notices

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D C, in regard to securing valid patent protection for their inventions Trade-Marks and Copyrights registered Design Patents and Foreign Patents secured

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

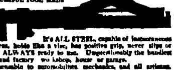
A New Wrench—and A Good Wrench

THE PERFECTION WRENCH
MOST USEFUL TOOL MADE



It's ALL STEEL, capable of instantaneous adjustment, holds like a vise, has positive grip, never slips or mars, is ALWAYS ready to use. Unquestionably the handiest tool around factory, workshop, house or garage.

Indispensable to automobilists, mechanics, and all artisans. Can be used as a vise, clamp, tool-holder, pliers, pipe or monkey wrench, INSTANTLY without change of parts.

The PERFECTION is made in three sizes, 8, 10 and 12-inch, and three finishes, polished steel, gun-metal, nickel. Prices range from $2.00 upwards. (Money refunded after three days' trial, if dissatisfied.) "You'll want one when you see it." For circular and price to trade address

We've taken prodigious pains to make this pen exactly right throughout.

FALCON ALUMINOID PEN

A new metal was invented—an alloy of aluminum that cannot rust. It makes a pen smooth, firm and springy.

Falcon Aluminoid pen prevents distracted thought, gives smoothness of action, holds much ink, makes writing easy.

The Comfort of the Telephone
AMERICAN TELEPHONE & TELEGRAPH CO.
LONG DISTANCE TELEPHONE
BELL SYSTEM
AND ASSOCIATED COMPANIES

The Bell System has become the *nervous system* of the business and social world.

The comfort it affords the women in the homes of America cannot be measured.

Do you measure it in considering the value of your Bell telephone?

The mother of children can find out where they are at any particular hour of the day—*and how they are*—even though their visits carry them to the country village or the city hundreds of miles away.

The husband on a trip talks from his hotel room to his wife at home.

There is a world of comfort in the *knowledge that you can talk together* at a moment's notice, wherever you may be.

The Bell telephone has a special value because it is everywhere—because at sight you feel a familiar acquaintance with a Bell instrument or a Bell sign.

There are over 4,000,000 Bell stations. You cannot use them all, but from time to time you have a real vital need for one. Which one you cannot foretell.

There are six billion calls over the telephones of the Bell System every year.

Many of these are comforting calls from afar, calls whose actual money value can no more be reckoned than the value of the happiness which one man has and another man cannot buy.

The *very existence* of the Bell telephone service has its value to you, even at moments when you are not using it.

The Bell Long Distance service offers, ready recruited for your call, the largest body of active business men in the world. If you have a telephone, avail yourself of its long distance possibilities.

The highest type of public service can be achieved *only by one policy, one system, universal service.*

Two Good Books for Steel Workers

Hardening, Tempering, Annealing and Forging of Steel

By JOSEPH V. WOODWORTH

Size 6¼ x 9¼ inches. 288 pages. 201 Illustrations. Price $2.50 postpaid

THIS is a practical work, treating clearly and concisely modern processes for the heating, annealing, forging, welding, hardening and tempering of steel, making it a book of great value to toolmakers and metal-working mechanics in general. Special directions are given for the successful hardening and tempering of steel tools of all descriptions, including milling cutters, taps, thread dies, reamers, hollow mills, punches and dies and various metal-working tools, shear blades, saws, fine cutlery and other implements of steel, both large and small. The uses to which the leading brands of steel may be adapted are discussed, and their treatment for working under different conditions explained; also special methods for the hardening and tempering of special brands. A chapter on case-hardening is also included.

The American Steel Worker

By E. R. MARKHAM

Size 6¼ x 9 inches. 367 pages. 163 Illustrations. Price $2.50 postpaid

THIS is a standard work on selecting, annealing, hardening, and tempering all grades of steel, by an acknowledged authority. The author has had twenty-five years' practical experience in steel-working, during which time he has collected much of the material for this book. Careful instructions are given for every detail of every tool. Among the subjects treated are, the selection of steel to meet various requirements; how to tell steel when you see it; [illegible] how to treat steel in the making of small tools, reamers, drills, milling cutters; [illegible] the best kind, and why; [illegible] a steel-worker would want to know [illegible] this book.

Concrete
Reinforced Concrete
—AND—
Concrete Building Blocks

Scientific American Supplement 1543 contains an article on Concrete, by Brysson Cunningham. The article clearly describes the proper composition and mixture of concrete and gives results of elaborate tests.

Scientific American Supplement 1538 gives the proportion of gravel and sand to be used in concrete.

Scientific American Supplements 1567, 1568, 1569, 1570, and 1571 contain an elaborate discussion by Lieut. Henry J. Jones of the various systems of reinforcing concrete, concrete construction, and their applications. These articles constitute a splendid text book on the subject of reinforced concrete. Nothing better has been published.

Scientific American Supplement 997 contains an article by Spencer Newberry in which practical notes on the proper preparation of concrete are given.

Scientific American Supplements 1568 and 1569 present a helpful account of the making of concrete blocks by Spencer Newberry.

Scientific American Supplement 1534 gives a critical review of the engineering value of reinforced concrete.

Scientific American Supplements 1547 and 1548 give a resume in which the various systems of reinforced concrete construction are discussed and illustrated.

NEW BOOKS, ETC.

RAILROAD STRUCTURES AND ESTIMATES. By J W Orrock, C.E. New York John Wiley & Sons, 1909. 8vo., 370 pp., 93 figures. Price, $4 net.

Under the title of Railroad Structures and Estimates, the intention is to cover in brief and concise form the numerous subjects that enter into the Engineer's Estimates of Railroad Building, for the purpose of ready reference, as to general construction and cost, on a business rather than a technical basis. As it is impossible to give the data to suit all conditions, the weights, quantities, and cost are given in detail in most instances, and may be varied as desired.

FRAMING. By William A. Radford. Assisted by Alfred S. Johnson, A.M., Ph.D., and Bernard L. Johnson, B.S. Chicago: The Radford Architectural Company New York Industrial Book Company 12mo., 388 pp. Price, $1.

To the carpenter especially, and to all others interested in wood in a structural way, this is a most important subject. The framing of a building has been likened to the skeleton of the human body It is important that it be put together properly and connected up in the right way The whole stability and success of the edifice depend on the strength and proper arrangement of the supporting frame. The present work is divided into four heads (1) Timber framing for houses, (2) barn framing, (3) framing of factories, stores, and public buildings, (4) miscellaneous framing, including strength of timbers and the principles of truss construction The work, accordingly will be taken up in this order In some cases certain subjects of an introductory or explanatory nature will be discussed, although, strictly speaking, they are no part of "framing" and possibly are not done by the carpenter Yet a knowledge of them will add to the carpenter's equipment, and will help him to do his work more intelligently

METAL SPINNING. Practical Instructions in a Fascinating Art. By Fred D Crawshaw, M.D Chicago Popular Mechanics, 1909 18mo., 72 pp Price, 25 cents.

Like so many of the other old-time crafts, the one of metal spinning has partially gone into disuse because of commercial competition and the failure of the younger generation of men to familiarize themselves with the handwork of their fathers. In the United States it is only in the larger cities that one finds an artisan who does metal spinning. When such a person is found, he is usually occupied in producing forms out of thin metal that require great care in making and are difficult to produce with the stamp or press. It is believed in some circles, particularly among metal spinners, that the pressing and stamping of metal can never fully take the place of spinning it. The object of this book is to assist amateurs in an interesting art, and also give practical metal spinners additional instruction.

THE SCIENTIFIC AMERICAN BOY AT SCHOOL. By A. Russell Bond. New York Munn & Co., Inc, 1909 Pp. 338. Price, $2.

One of the most interesting and helpful of recent books for boys was "The Scientific American Boy," by the accomplished author of the present volume, in which was described the adventures of a youth of mechanical turn of mind with his companions in a vacation season Mr Bond now carries the story further, places his hero in boarding school, and invites his readers to enjoy his later adventures, and profit by them as well. It is pre-eminently a boy's book for boys, for boys with sound bodies and healthy minds, who like to be out of doors and making things with their hands—just the kind of boys one reads about and would like to have or know, but who sometimes seem rather scarce when one scans the list of one's boy acquaintances. Mr Bond has been more fortunate than some of us, for his boys are fine young chaps, full of life and vigor and endowed with mechanical turns of mind that must have given some of their elders pause But at all events they are not prigs, but good, wholesome boys of the right sort, and if one does not meet them in the streets every day it is good to know there are such young people and to read about them in Mr. Bond's agreeable pages. The book is not at all a history of school life, but might be scientifically described as an essay on surplus energy It deals, not with what the boys did in school hours, but what they did outside of them. These, of course, are the real hours of a boy's life, the time in which he is free and unrestrained, in which he seeks to please himself and work off some of that boy energy that is sometimes not always so appreciated by his elders as it might be. So the book brims over with good nature and ingenuity and with the breath of outdoor activity If the mechanical performances of these young fellows seem sometimes a bit audacious, we may rest assured, with the author's certificate, that they never did anything boys of real earnestness and ingenuity could not have accomplished. The careful parent may perhaps be disposed to pause a little at the flying machine, [illegible] Mr. Bond and find out what happened. The book is agreeably written with a sympathy for boy life and boy [illegible]

Just Published—A BOOK OF INTEREST TO RIFLEMEN

The Bullet's Flight from Powder to Target

The Internal and External Ballistics of Small Arms. A Study of Rifle Shooting with the Personal Element Excluded, Disclosing the Cause of the Error at the Target.

Illustrated with one hundred and eighty-eight plates, showing the results of over three hundred rifle experiments performed and chronologically arranged

By F. W. MANN, B.S., M.D.

Size 7½ x 9¾ inches. 384 Pages. Price $4 00 postpaid

THIS is a thoroughly practical treatise and deals with a subject the literature of which is not commensurate with its importance or interest, and it possesses unusual value, not only because it furnishes a large amount of information, of a very practical kind, but because this information is the result of a practical experience on the part of the writer extending over a period of thirty-eight years. The results of the author's experiments, as here given, have been persistently and laboriously worked out with an earnest desire to assist his fellow marksmen. In view of the fact that conjecturing and theorizing have been so prevalent in rifle literature, the work has been kept free from speculation, except where they have either been proved to be false or have been fully substantiated by recorded experiments. Most of the illustrations are photographic reproductions of the results of actual tests. Every page is full of interest for the rifle enthusiast. There is a full discussion of various kinds of rifles, of the effect of differences of length, of variations of rifling, etc., as well as of instructive experiments such as that of venting the barrel near the muzzle. An idea of the contents may be gathered from a few of the subjects treated, such as the Personal Element vs. Mechanical Rifle Shooting; Utility of Vented Barrel; High-Pressure Sharpshooting Powder; Telescope Mounts; Ruined Rifle Bore vs. Smokeless Powder vs. Primers; Accurate Ammunition Difficulties; Flight of Bullets; Gyration and Oscillation; Motions Executed by Normal Flying Bullets; Determining Rifle Twists; Kinetics of Spin, etc. In many respects this work is unique in the literature that has been published on this subject. It is a thoroughly practical work and will be found to be of very real value to those who are engaged in a study of the ballistics of the rifle with a view of improving the all-around efficiency of that weapon.

MUNN & COMPANY, Inc., Publishers, 361 Broadway, New York City

who wishes to interest his boy in the value of thinking and doing. The numerous illustrations are extraordinarily helpful and practical.

Handy Man's Workshop and Laboratory. Compiled and edited by A. Russell Bond. New York: Munn & Co., Inc., 1909. Pp. 467. Price, $2.

This is a book of first rate importance and interest, and is a notable contribution to practical work from the office of the Scientific American. It is a book that not only aims to be practical but which is practical from cover to cover. It is a collection of ideas and methods, of ways to do things, of what to do and how to do it, as proposed, tried out, and tested by resourceful men, both amateur and professional. It contains, in short, upward of a thousand ingenious "kinks," ideas, and hints, useful to the household, attractive to the mechanic, and interesting to everyone who loves to tinker and make articles of use and value, or in whom the spirit of experimentation is inbred. Unlike many books of this kind, however, this is no collection of scientific experiments. In fact it is not an experimental book at all, but a treatise of useful things. It is not concerned with theory, but with fact. It deals, not with what will give curious results, but with achievements of real value and utility. And this it does in the most direct way possible. The descriptions of methods are concise and clear, and at every point they are supplemented with drawings and diagrams, many of which are in the form of working drawings that show, in a very precise and definite way, just what to do, and how to do it. There are 370 such illustrations in the book, very clearly drawn and lettered, and illustrations that illustrate in the best sense of the word. The origin of the book is a department established some time ago in the Scientific American, devoted to the interests of the "Handy Man." A flood of suggestions poured in from a multitude of sources, and the best of these have been reproduced in the present volume. It is, however, in no sense a reprint from the Scientific American, since much of its contents is now printed for the first time. Mr. Bond has devised a book that will very successfully appeal to a very wide circle. The amateur workman is attracted by the opening chapter on fitting up a workshop. Both he and the professional mechanic will find a host of suggestions on the greatest diversity of topics in the next chapter on Shop Kinks. Both again will be interested in the very valuable chapter on the soldering of metals and the preparation of solders and soldering agents. Here is a long list of formulas for solders of tried and tested accuracy. The professional mechanic is especially appealed to in the fourth chapter on the Handy Man in the Factory, while still another class of readers will be interested in the fifth chapter on the Experimental Laboratory. Electricity is very fully treated in the sixth chapter, and the householder will find a wealth of suggestion in the numerous devices described in the seventh. The sportsman will be helped with the hints of the eighth chapter, while the final chapter on flying machines is of the greatest possible present-day interest. It is, in short, a book of the widest general interest, and both editor and publisher are to be heartily congratulated on the success obtained in this very valuable publication.

Concrete Pottery and Garden Furniture. By Ralph C. Davison. New York: Munn & Co., Inc., 1909. Pp. 196. Price, $1.50.

The publishers' statement that this is a new book on a new subject is very true. Neither concrete pottery nor concrete garden furniture is in itself new, but a book dealing with their making by the amateur has not heretofore been published, and hence this volume amply supports the claim of novelty made for it. Readers of American Homes and Gardens have already acquired some familiarity with Mr. Davison's guidance in this fascinating art, and while the articles he contributed to these pages have been reproduced in this book, they have been given a new form and much new and additional matter has been added to them. The illustrations have been greatly increased in number, and the whole given the form of a practical handbook. Books on handicraft of any kind are apt to fail, more or less, in the inadequacy of their directions. The author, too, often knows so well what to do and how to do it as not to realize that those who have not followed the work before may not quite follow what are supposed to be careful directions. Mr. Davison has been fully alive to this misfortune in books of this kind, and has, therefore, taken especial pains to make his descriptions most accurate and detailed. No other method is, of course, really feasible; but it is seldom this sort of thing has been so well done as in his pages. The careful text is supplemented with illustrations as carefully made and lettered, so that the book is a genuine handbook of craftwork, thoroughly practical in every part, and admirably adapted to its special purpose of explaining every portion of the work involved in the production of the various articles described. Mr. Davison has opened up quite a new field for the amateur. The materials required are abundant and cheap, the methods in the simpler pieces at least, easy and devoid of difficulties. And the work is not only pleasant, but the results are agreeable and decorative. The author thoroughly knows and understands his subject, and has the gift of imparting his knowledge to his readers.

KOH-I-NOOR Pencils cost you 10c each or $1 a doz. Pay less and you get less.

L. & C. Hardtmuth KOH-I-NOOR Quality

The Standard of Pencil Quality throughout the world. 17 different degrees of hardness and softness (6B to 8H) and two copying degrees. If your stationer will not supply you—write to us.

Maurice Hewlett

The New Serial in Scribner's Magazine beginning in January 1910

Rest Harrow By Maurice Hewlett

The author is one of the foremost and most widely read and admired writers of to-day. This story possesses all of his fascinating qualities of poetry and romance and the interest of character revelation, together with a strikingly original point of view that will attract and hold the attention from the very beginning. It is a modern story, a view of life as the author sees it to-day, and its truth, beauty of style and fearlessness, with a characteristic note of unconventionality and humanness, will make it one of the most remarkable serials the Magazine has ever published.

Dash box, combinable, [illegible]	[illegible]
Denaturant, [illegible]	[illegible]
Dough mixing machine, [illegible] Chambers, Jr.	[illegible]
Draft appliance, O. Alstead	[illegible]
Duster, C. W. Diehl	[illegible]
Dust shield, E. J. Kiebert	[illegible]

[illegible] machine, lace [illegible] mechanism for straight, Baker & Whitney	939,[illegible]
Lacing tips and the like and composition for the same, fabric for, G. W. Prentice	939,918
Lamp, carriage, H. Blau	939,285
Lamp, gas or vapor electric, P. C. Hewitt	939,913
Lamp, mercury and other vapor electric, Kent & Lobell	939,708
Lamp, miner's electric, H. Bomann	939,690
Lantern, J. H. Pease	939,542
Lantern and heater, combination, G. H. Armington	939,377
Last, locking collapsible, C. P. Pym	939,960
Last, shoe, A. J. Bush	939,213
Lattice tool joint, C. L. Libby	939,722
Lawn rake, rotary, C. Waits	939,765
Lead joint runner, W. Vanderman	939,906
Lens carrier, lantern, F. D. Spear	939,704
Lens grinding machine, automatic prescription, E. O. Mattern	939,645
Leveler, automatic, E. Woodward	939,372
Lever, J. R. Weatherly	939,574
Lifting jack, F. W. Allerton	939,374
Lighting and extinguishing device, automatic, A. J. Bedford	939,790
Line casting machine, J. McNamara	939,291
Line casting machines, keyboard mechanism for, J. R. Rogers	939,835
Line slug trimming machine, S. B. Carter	939,809
Linotype machine, F. Johanneson	939,269
Liquid as a motive power, method and means of utilizing, B. Taylor	939,787
Liquid cooling and dispensing apparatus, G. W. & W. H. Palmer	939,964
Liquid dropper, R. K. Scott	939,736
Liquid fuel burner, E. Moore	939,612
Liquid fuel lighting system, A. Burton	939,799
Lock bolt, L. & D. Mueller	939,921
Lock key, L. C. Freed	939,679
Locks, seal attachment for, C. H. Johnson	939,699
Loom filling detector mechanism, G. F. Hutchins	939,[illegible]
Loom filling detector mechanism, weft replenishing, E. H. Ryon	939,954
Loom pattern mechanism, Owen & Pratt	939,399
Loom picker stick mechanism, L. P. Sherman	939,590
Loom shuttle, Cunniff & Rafferty	939,892
Loom, weft replenishing, E. H. Ryon	939,836
Looms, filling thread cutting device for weft replenishing, B. F. McGuiness	939,483
Looms for weaving, beating up mechanism of, W. Holtes	939,508
Loss preventing device, M. T. Fish	939,497
Lubricant, J. W. Watkins	939,645
Lubricating device, F. R. Paine	939,501
Magneto generator, R. H. Hamlet	939,910
Mail bag deliverer, S. B. Colbert	939,896
Mail catcher and deliverer, railway, W. T. Sebree	939,587
Mail delivering and receiving device, J. A. Bowie	939,793
Mail delivering apparatus, J. T. Howard	939,289
Mail delivering appliance for railway trains, H. J. Hill	939,668
Mail pouch catching and delivering apparatus, J. A. Gibbs	939,786
Manhole closure, C. C. Puffer	939,028
Massage and air compressing machine, J. B. Fey	939,839
Match box, automatic, J. G. Hanna	939,262
Match holder or safe, H. M. King	939,710
Match machine, W. R. Swett	939,349
Match safe, pocket, J. F. Beatty	939,697
Matrices, dovetail notch chamfering machine for, H. A. Reynolds	939,682
Matrix channeling machine, H. A. Reynolds	939,681
Matrix combination punching machine, H. A. Reynolds	939,683
Measurer, liquid, C. C. Allen	939,195
Metal box, Kleck & Fink, reissue	13,028
Metal shears, G. Poistada	939,627
Metallic tie, T. B. Bradford	939,704
Micrometer, H. Spahn	939,562
Milk, desiccating, F. X. Govers	939,496
Milk heater, H. C. Root	939,998
Miter gage, Erikson & Wikander	939,405
Mold, J. N. Erixon	939,819
Molding flask, J. D. Millar	939,849
Molding mechanism, W. Simmerman	939,541
Mop, Wichmann & Rich	939,888
Mower trimming attachment, lawn, H. Smith	939,986
Music turner, W. & R. Mark	939,525
Musical instrument strings, holder and protector for, O. J. Muller	939,794
Musical instrument tracker mechanism, T. F. Brown	939,867
Net frame, landing, G. M. Barnes	939,881
Nut lock, W. Atkins	939,654
Oil and grease gun combined, F. J. Ball	939,466
Oil burner, C. Eckland	939,816
Oil cake forming machine, A. W. French	939,489
Oiling device for gas meter diaphragms, automatic, J. E. Daly	939,675
Ore separator, magnetic, W. D. Ludwick	939,829
Oven, bake, B. A. Geurink	939,410
Packaging machine, B. W. Tucker	939,358
Packing and display receptacle, W. E. Collins	939,607
Painting machine, wheel, J. Holm	939,416
Paper box blank machine, J. R. Van Wormer	939,571
Paper cutter and printer, automatic roll, G. V. A. Pine	939,545

IT'S SUMMER NOW IN JAMAICA

"THE LAND OF SCENIC AND CLIMATIC PERFECTION"

To add to the delightful charms of a winter vacation in Jamaica and the West Indies, and to experience the pleasures of luxurious voyaging, make the ocean trip on one of the superb 6,000-ton PRINZ steamers of the ATLAS SERVICE, (Hamburg American Line), sailing weekly from New York.
These vessels offer all the comforts and conveniences of of our well known trans-Atlantic steamers, They are ideally adapted for this service
Commodious and home-like staterooms, splendid saloons, spacious decks, excellent cuisine.

RATES TO JAMAICA: { One Way $45.00 / Round Trip $85.00

Also cruises of 3 weeks duration and longer, calling at Jamaica, Colon (Panama Canal), Savanilla, Cartagena, Santa Marta, Port Limon, Costa Rica

Leave New York every week. Rate, including stateroom accommodations and meals, $125 upwards.

Send for Booklet giving full particulars.

Hamburg-American Line 41-45 Broadway, N. Y.
Boston Philadelphia Chicago St. Louis San Francisco

THE "BEST" LIGHT

Produces a pure white, powerful steady light, is absolutely safe, and brighter than electricity or acetylene—cheaper than kerosene. NO GREASE, DIRT, SMOKE OR ODOR. Makes and burns its own gas. Made in over 100 different styles. Every lamp warranted. Write for catalog. Agents Wanted.
THE BEST LIGHT CO., 87 E. 5th St., Canton, O.

SCRIBNER'S MAGAZINE 1910

THEODORE ROOSEVELT'S own and exclusive account of his *African Trip* will continue to be a very important feature of the Magazine during a greater part of 1910.

The articles already published have met every expectation with regard to their exceptional interest and value, and the extraordinarily large editions required to meet the demand have had to be increased with each number. Nothing he has ever written has better revealed his own attractive personality, his remarkable faculty for observation and appreciation of the picturesque and unusual in both humanity and nature. The *Boston Transcript* says:

"Mr. Roosevelt has a unique way of feeling as the American nation feels. His general sympathies, modes of thought and emphasis, and even his prejudices are largely theirs. That fact makes Americans follow with zest the story of his hunting in the wilds, told with the same grim strength that has made his political utterances so far-reaching and deep in their influences."

In the January number he will describe hunting experiences at,

Juja Farm: Hippo and Leopard

These articles are not only fascinating narratives of adventure, they are also authoritative accounts of the natural history of many animals but little known to most readers. The illustrations by Kermit Roosevelt and other members of the expedition are especially interesting. To secure all of Mr. Roosevelt's articles subscriptions should begin with the October number.

THE WELLCOME TROPICAL RESEARCH LABORATORIES AT KHARTUM.

(*Continued from page 375*)

under the direction of Dr C N Wenyon, proto-zoologist to the London Tropical School of Medicine, and proved such a complete success that the work in this direction is being considerably developed

Entomology is another very promising science that has claimed considerable attention in these laboratories There is an immense field in the Sudan for an economic entomologist, and the scope and variety of the work done is almost bewildering. There are pests of every kind infesting every living being and plant, and the task of reducing these would at times seem almost hopeless. Every year taxes aggregating large sums, have to be remitted owing to the ravages of *Aphis sorghi* and other pests Fatalism, natural indolence, and improvidence often prevent the natives, unless supervised, from taking those active measures so necessary in cases of insect infestation of crops. These labors have also a direct bearing on tropical medicine, as results have abundantly testified

In the field of anthropology very valuable work has been accomplished. The laboratories are recognized as a working place for fellows of the Carnegie Research Fund, and on the recommendation of the director, Dr A. MacTier Pirrie was appointed anthropologist to the Institution. In addition to his medical qualifications, Dr Pirrie held a special degree in anthropology, and was particularly well versed in physical work Although he labored under the great disadvantage of not knowing the country he undertook and successfully completed remarkable journeys into the totally unknown Burun country, which lies between the White Nile and Abyssinia. He lived and moved among the tribes inhabiting this territory, and his method of handling the natives was highly appreciated by the government By his free movement among them he was able to acquire extensive data of their life, manners, and customs of the most highly prized character Unfortunately, these expeditions proved fatal to the young, enthusiastic investigator During one journey he contracted an indigenous disease propagated by the parasite of kala-azar He was prostrated and invalided home to Scotland but died six months later before he had the opportunity of setting out the results of his work. His notes and observations, as well as those of archæological and ethnological aspect were worked up by competent authorities and have thrown much light upon a people and their country about which nothing has previously been known

The chemistry section has received as much attention as tropical medicine, for it has an important bearing upon the commercial development of the country The principal fields of investigation in this direction have been Sudan gums, food-stuffs, and seeds, as well as water supply from the Blue and the White Nile and wells. The study of gums has been particularly exhaustive. The Sudan has extensive forests of gum trees in fact, such constitutes one of its staple products. Inquiry showed that comparatively little was known about gums so that great attention was concentrated upon this subject. After some four years of labor, the laboratories have made some valuable additions to the chemistry of this commodity, and it is hoped that their labors may result in placing the Sudanese gum industry upon a sound basis

Unfortunately, on May 11th 1908, the laboratories suffered a heavy calamity in a fire, which breaking out in the photographic dark room practically gutted the building, except the library, directors room, and one or two other departments Not only was a very large quantity of equipment destroyed but all the trypanosomiasis specimens were lost, together with the records of two years work on the subject. Nearly all the paraffin blocks prepared during the previous

(*Concluded on page 383*)

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES

ANYONE, anywhere, can start a mail order business at home. No canvassing. Be your own boss. Send for free booklet. Tells how. Heacock, [illegible], Lockport, N. Y.

Inquiry No. [illegible].—Wanted to buy nickeloid for buttons.

HELP WANTED

WE WANT LOCAL REPRESENTATIVES in every city, also salesmen to handle a lighting system which makes and burns its own gas. Much cheaper and superior to gas or electricity. For full particulars address Gilbert Light, 5 W. Michigan St., Chicago.

Inquiry No. [illegible]. For the address of the W[illegible] Mfg. Co., manufacturers of waterproof collars and cuffs.

WANTED. Marine Engineer with capital to invest, capable of taking the management of machine shop in steel ship building plant now under construction. For particulars address Post Office Box [illegible], Vancouver, B. C.

Inquiry No. [illegible]. For manufacturers of "Wyatt's Electro-Catalytic Sparking Plug."

PARTNERS WANTED

WANTED. Partner with sufficient capital or a business firm, to cooperate on to manufacture article under Patent No. [illegible], or royalty basis, or for sale. Goods are staple and cheaply made. Partner, Box [illegible], N. Y.

Inquiry No. [illegible]. Wanted the manufacturers of the Van Winkle Woods & Sons and the Weber power motors.

PATENTS FOR SALE

FOR SALE.—Patent No. [illegible]. Improvements on [illegible]. For further information write to A. G. Labbe, 852 Clayton Street, San Francisco, Cal.

Inquiry No. [illegible]. Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE. Patent No. [illegible]. An improved lathe rest for holding cylinders while being bored in an engine lathe. For further particulars address A. E. White, Weston, W. Va.

Inquiry No. [illegible]. For information regarding shoes not made of leather but similar to the same and are as durable.

PATENT FOR SALE. Combination trunk and typewriter desk; a very useful device for travelers. The change can be made in a minute from a trunk to office desk, with typewriter in place and [illegible] remove typewriter and [illegible] and you will have a [illegible] table useful [illegible]. I will sell the patent [illegible] right [illegible] license to manufacture on royalty. U. S. Patent No. [illegible] April [illegible]. Address M. R. Schultze, Southampton, N. Y.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

THE SANBORN BAG LIFTER. A device to assist in handling bags of grain, cement, etc. Saves the fingers and avoids damage to bag. Sample sent free on request. H. & E. Sanborn, Portland, Maine.

Inquiry No. 9016. Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

FOR SALE

FOR SALE. Engine lathe, swings 9½ in., takes 28 in. between centers. Complete with full set change gears. [illegible] Address L. F. G[illegible] & Son, [illegible], Iowa.

Inquiry No. 9024. Wanted to buy silk machines from raw reel to twisting and doubling to the final process of making it into cloth.

SITUATIONS WANTED

MECHANICAL ENGINEER. Graduate Karlsruhe Polytechnical University; 31 years of age; two years practical experience; will exhibit best references. Desires immediate employment. Address E. F. Neubert, 88 Garfield Place, Brooklyn.

Inquiry No. 9025. Wanted address of rubber manufacturers in Germany.

MISCELLANEOUS

"LIGHT, HEAT, MAGNETISM AND ELECTRICITY are all one and the same thing." If you want to know what they are send fifty cents for a copy of this pamphlet to A. E. Howland, El Paso, Texas.

Inquiry No. 9034.—Wanted, to buy a washing machine that is run by a coil spring motor.

HAIR GROWS when our Vacuum Cap is used a few minutes daily. Sent on 60 days free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., 588 Barclay Block, Denver, Colo.

Inquiry No. 9039. Wanted catalogues and all information on machinery for braiding straw in manufacturing straw hats.

LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9031. For manufacturers of machinery that could reduce stumps to kindling wood.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9036. Wanted the address of the manufacturers of "Tyre Ball Bearing Suspenders."

Inquiry No. 9038. Wanted the address of the Chapman Electric Purifying Co.

Inquiry No. 9040. Wanted the address of Farney Safety Razor Co.

Inquiry No. 9042. Wanted the address of the manufacturers of mirrors that are transparent when the light in the rear is stronger.

Inquiry No. 9044.—Wanted to buy outfits necessary for opals polishing.

Inquiry No. 9045.—Wanted the address of the [illegible] Lumber and Development Co., manufacturers of hardwood.

MODEL 19—$2000

The only car of Established Reputation at a Moderate Price

If there is any probability whatever of your buying an automobile for 1910, you ought to see this remarkable car before making your purchase.

Everything about it represents the refinement of construction, together with running qualities that are a revelation to those who have owned other cars.

This Model 19 is not made to sell in big quantities, and dealers have **already placed definite orders for all the cars we can build.**

We strongly advise those who are contemplating the purchase of a car of this character, to get in touch with us immediately. Brochure giving full details sent on request

THE CENTURY PLAN OF LIBRARY-BUILDING MEANS

A SAVING OF MONEY
" " " TIME
" " " SPACE

An Honest Effort along carefully thought-out lines to provide the reading public with books strictly worth while

WHY SPEND all your spare money on the complete works of ONE author and cumber your library shelves with many books which you will never read, when for the same money or less, you can get the chief works of a number of authors by taking advantage of this plan?

The Only Plan for the Practical Man or Woman

Exercise the same intelligent discrimination in planning your library as you would in planning the other details of your home

UNITS OF 7	*SETS NOW READY*	
GEORGE ELIOT *7 Vols., 28 Illustrations*	A beautiful edition of this popular author. Typographically perfect. Pictorially superb. Vol. I Adam Bede; II Romola; III Romola, Silas Marner; IV The Mill on the Floss; V Felix Holt; VI Middlemarch; VII Middlemarch	Value $14
BALZAC *7 Vols., 28 Illus.*	Twenty of the great masterpieces of Balzac's "Comedie Humaine" (Human Comedy), in which he pictures every phase of French life and character under the classifications Scenes of Private Life, of Provincial Life, of Parisian, of Military and Country Life, and Philosophical Studies.	Value $14
HUGO *7 Vols., 28 Illus.*	Among the greatest productions of literary genius, Les Miserables is easily the most imposing literary monument of the Nineteenth Century. I-V Les Miserables—1 Fantine; 2 Cosette; 3 Marius; 4 Saint Denis; 5 Jean Valjean; VI Notre Dame de Paris; VII Ninety-Three.	Value $14
WASHINGTON IRVING *7 Vols., 28 Illustrations*	Notable for the beauty of its illustrations by celebrated modern artists—Remington, Dinedinst, Castaigne, Du Mond, Kemble, F. O. C. Darley, etc. Twelve titles, including Sketch-Book, Knickerbocker's History of New York, Bracebridge Hall, Crayon Papers, Tales of a Traveler, The Alhambra, Astoria, etc.	Value $14
DUMAS' VALOIS ROMANCES *7 Vols., 28 Illustrations*	Some of the finest creations of Dumas are introduced in these romances which present a vivid picture of the France of the Huguenots. I Marguerite de Valois; II Catherine de Medicis; III La Dame de Monsoreau; IV Chicot the Jester; V The Forty-five Guardsmen; VI Henry of Navarre; VII The Conspirators.	Value $14
AINSWORTH'S HISTORICAL ROMANCES *7 Vols., 28 Illustrations*	Thrilling stories of the most dramatic periods of English history with the famous illustrations of George Cruikshank. Vol. I Windsor Castle, A Romance of the Reign of Henry VIII; II-III Tower of London—1 Jane the Queen, 2 Mary the Queen; IV-V Guy Fawkes—1 The Plot; 2 The Discovery; VI-VII Jack Sheppard, Part 1; Jack Sheppard, Part 2.	Value $14
EUGENE SUE *7 Vols., 28 Illus.*	The author of The Mysteries of Paris and The Wandering Jew has had hosts of imitators, but in the realm of pure, unbiased romance he still remains without a peer. The Wandering Jew, Vols. I-IV—1 Inn of the White Falcon; 2 Hôtel de Saint-Dizier; 3 The Protector; 4 The Cholera. The Mysteries of Paris I-II—1 The Tapis-Franc; 2 Rigolette; 3 Doctor Griffon.	Value $14

Note These are all Century Library Editions, which means good paper, clear type, and beautiful illustrations. The binding is a silk-finish ribbed cloth, with titles on labels stamped in gold and finished with gilt tops and trimmed edges. A different color scheme has been used with each set.

HOW TO ORDER [illegible]

THE CENTURY CO., [illegible]

[illegible] examined the incubator [illegible] of micro-organisms were lost, and thus a far-reaching investigation has been temporarily arrested, and it has not yet been possible to replace the material. Upon the receipt of the news of the catastrophe, Mr. Henry S. Wellcome, to whose munificence the Institution was due, immediately offered to replace the lost equipment, and through his generosity the laboratories were completely refitted and re-equipped with the most modern appliances, so that work could be resumed with the minimum delay. Consequently, so far as general usefulness goes, the Institution was only temporarily crippled.

Work is now again in full swing, and it should be pointed out that there is a very large field to be covered yet. If the various countries interested in the exploitation of the continent could establish similar laboratories to this in their respective territories, it would soon become a white man's land, and through concerted action the terrible maladies which at present arrest development would be completely subjugated.

◆

ARTILLERY FOR AIRSHIP ATTACK.

(Concluded from page 373.)

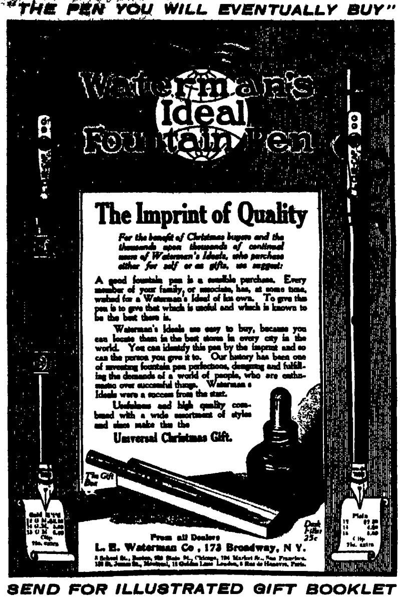
is clamped tight against the axles. The third type of cannon is of a much heavier build than the two which precede, seeing that in this case it is designed to be mounted on shipboard, and hence the weight does not need to be reduced as in the other cases. It is of a considerably larger caliber, this being 10.5 centimeters (4.2 inches). In most of the details it is designed on the same lines as the second type. It is intended to be mounted generally upon torpedo boats or swift cruisers, and naturally the gun can be brought into service as an ordinary cannon in cases where it is needed. For the gun proper, the weight is 3 080 pounds, while the support weighs 3,520 pounds, giving a total weight of 6 600 pounds for this type. Like the former, the angle of elevation is 75 degrees at a maximum. The projectile, weighing 40 pounds, has an initial speed of 2,300 feet per second. A horizontal range of 44,500 feet is reached in this case, and we have the unusual height of 37,620 feet.

The present types of gun were given a series of tests by firing upon captive balloons, and two of our engravings illustrate this feature. In one case we observe the balloon, which has not been hit by the shot, and this can be clearly seen by the trail of smoke which shows the path of the projectile. In the second view is represented the effect which takes place when the projectile strikes the balloon, and we have the detonation of the grenade and at the same time the explosion of the gas and the destruction of the balloon.

◆

Alcohol vs. Gasoline Engines.

Almost any engine with a well-designed carbureter will run as well with alcohol as with gasoline, except for a difference in ease of starting and in certainty of operation at low speeds. By using alcohol in an alcohol engine with a high degree of compression the fuel-consumption rate in gallons per horse-power hour can be made practically the same as for gasoline in a gasoline engine of the same size and speed. An alcohol engine with the maximum compression for alcohol will have 30 per cent more available horse-power than a gasoline engine of the same size, stroke, and speed, and the weight per horse-power may be less. [illegible]



"THE PEN YOU WILL EVENTUALLY BUY"

Waterman's Ideal Fountain Pen

The Imprint of Quality

For the benefit of Christmas buyers and the thousands upon thousands of continual users of Waterman's Ideals, who purchase either for self or as gifts, we suggest:

A good fountain pen is a sensible purchase. Every member of your family, or associate, has, at some time, wished for a Waterman's Ideal of his own. To give this pen is to give that which is useful and which is known to be the best there is.

Waterman's Ideals are easy to buy, because you can locate them in the best stores in every city in the world. You can identify this pen by the imprint and so can the person you give it to. Our history has been one of inventing fountain pen perfections, designing and fulfilling the demands of a world of people, who are enthusiastic over successful things. Waterman's Ideals were a success from the start.

Usefulness and high quality combined with a wide assortment of styles and sizes make this the

Universal Christmas Gift.

The Middle West Number of the SCIENTIFIC AMERICAN

On December 11th, 1909, the Scientific American will issue a number devoted entirely to the wonderful Middle West region of the United States, a number which will set forth broadly and lucidly not only the agricultural interests of that region, but also those larger engineering undertakings which are destined to transform the Middle West in part at least, into a manufacturing territory.

With that object in view the Middle West Number will publish articles on the following subjects:

I. The Chicago and Gulf Waterway.—An illustrated description of Chicago's drainage canal, an engineering work which stands without a parallel in the world.

II. Chicago as a Railroad Center.—Chicago is the greatest railroad center in the world.

III. The Wonderful Grain Trade of Chicago.—Chicago is an enormous wheat bin, into which most of the grain raised in the middle West is poured.

IV. Shipping on the Great Lakes.—Most of the iron ore that is now smelted in Pennsylvania is mined in the middle West. To transport it to the blast furnaces of the East at a cost which will enable American steel makers to compete with foreign steel makers, it has been necessary to devise a new kind of lake transportation. Ships of [illegible] and [illegible] tons burden have been constructed which convey ore at small cost through the Great Lakes, and which are without a counterpart anywhere in the world.

V. The Handling and Shipment of Iron Ore.—The above-mentioned fact that iron ore is mined in the middle West and smelted in the East has necessitated not only the construction of special freight-carrying steamers, but also the designing of special machinery for loading and unloading the ore from the steamers.

VI. Freighting on the Mississippi.—Freighting on the Mississippi is a more important industry than most of us may realize.

VII. The Steel Industry.—One of the greatest steel plants in the world is that which has been built at Gary.

VIII. The Freight Subway System of Chicago.—Chicago can boast of a rational system of handling freight by means of subways.

IX. The Water Supply of Chicago.—Chicago's source of water is Lake Michigan. The city is supplied with water by means of a tunnel which extends two miles out into the lake.

X. Reclaiming Arid Lands.—The United States Government has under way many irrigation projects for the purpose of reclaiming lands which are arid, but which will blossom if properly watered.

XI. Harvesting the Grain of the Middle West.—Farms that cover not acres but square miles, crops that aggregate not simply bushels but car-loads, have rendered it necessary to plant and harvest on an unprecedented scale in the middle West. The ingenious agricultural machinery which has been designed to cope with these peculiar conditions is described and illustrated.

The Middle West Number will be more than twice the size of the regular SCIENTIFIC AMERICAN. It will be lavishly illustrated. It will be contained in a colored cover which strikingly depicts Chicago's grain elevators at work. Order from your newsdealer or from

Big Money In Drilling

Our customers all over the Country are making from $25 to $75 profit a day with the Cyclone Drill. No business offers such big returns for the money invested.

Contractors, prospectors, well drillers, find the Cyclone Drill more economical, faster and easier to operate than any other.

We make Hollow Rod, Cable and Core Drills, to meet every need.

We also make combination machines that will handle any or all of the systems equally well—a machine that will enable you to cover the entire field of drilling.

Cyclone Drill

Our Diamondite and Steel Shot Core Drills cut faster and at fraction of the cost of the old [illegible] drills. We sell Cyclone Drills on an *easy payment plan*. Some of our customers have made more than the price of the machine within one month. Our new traction Gasoline machine—only one made—is of particular value where fuel and water are scarce. Send for our free books on Drilling, and let us know in what branch of the work you are interested.

PRESENT CONDITIONS ON THE PANAMA CANAL.

A careful reading of the Annual Report of the Isthmian Canal Commission, now before us warrants the statement that, save for some extensive and troublesome slides in the Culebra cut, the whole of this great work of engineering and administration is prosecuted without mishap, and with every prospect of its completion by the year 1915

During the year the designs for the upper locks at Gatun and the locks at Pedro Miguel were completed. The locks are built in pairs, separated by a solid wall 60 feet thick they are 110 feet in width and have 1,000 feet of usable length They will be emptied and filled through lateral culverts under the floors, connecting with large longitudinal culverts in the side and center walls operated by Stoney valves In all plans for the canal, it has been laid down as a fundamental feature of design that at each pair of locks there must always be two barriers separating the high level from the level next below The extra or collision barrier consists of a set of hinged, vertical, mitering gates, and a massive chain barrier controlled by capstans in the walls. As over 95 per cent of the vessels of the world are less than 600 feet long, intermediate gates have been introduced dividing the lock chambers into two parts suited to vessels 550 and 350 feet in length respectively The intermediate gates are also protected by a chain barrier An emergency dam, which will cut off the flow of water in the event of a gate being carried away will be provided at the head of the locks. The design consists of a swing bridge from which girders, supporting specially designed wickets are lowered the bottom of the girders resting on sills at the bottom of the lock

The various materials of the foundations for the locks have been tested by trial loads and found to have sufficient resistance to carry safely the greatest loads that will be brought upon them by the structures. Curtain walls will be built to stop any underflow and to prevent the concrete floors being lifted by the pressure of any water which might gather below them, they are being thickened and anchored down to the underlying sandstone by the old rails left from the French administration The plant for the rock crushing and the mixing of the concrete is installed and in successful operation Concrete laying has commenced, and by the last of October 41,236 cubic yards had been put in place

Reference is made in the report to the sensational rumors of bad slides which were sent out at one time from Panama. They were occasioned by a subsidence of no consequence whatever, which occurred to one of the rock fills at the toe of the Gatun dam It is admitted that the most practical question in the construction of the dam is the sliding of the material underneath and in the body of the dam The question of its sliding depends upon the slope of its outer face, and since the dam which has a height of 115 feet above sea level, has more than a mile of horizontal thickness at its base the Report is certainly justified in stating that the stability of this great work goes far beyond the limits of what would be considered sufficient and safe in any less important structure. The excavation for the spillway in the center of the dam is completed, and the channel below the dam, 960 feet long and 285 feet wide, is being concreted.

The dredging fleet has removed from the channel between the Gatun dam and deep water in the Caribbean Sea, a total of over 6,000,000 cubic yards, and at the present time some three miles of the channel from deep water (41 feet at mean tide) have been completed. Limon Bay, through which the entrance to the canal will be made, is exposed to strong winds and heavy seas. To protect the entrance channel, two breakwaters, one 10,000 and the other 3,500 feet in length, are to be built.

In the central division, including the basin at Gatun Lake and the great Culebra cut, progress has been very satisfactory Although the Report covers the year only up to June 30th, we may add that on October 23rd, when 39,022,299 cubic yards had been excavated, the work that remained to be done in the Culebra cut when the Americans took over the work was half completed Including the work done by the French, this means that two-thirds of the whole work has been done Slides in the Culebra cut continue to be a source of annoyance One of these measures 2 700 feet along the cut, and involves about 27 acres of moving material Already 677 000 yards have been removed, and as much more is still in motion There are smaller slides which bring up the total amount of material in motion to 1,000,000 cubic yards. These slides will necessitate easier slopes to the cut at the points where they occur, and will add to the total yardage, otherwise they will have no effect upon the canal

In the Pacific division, the locks at Pedro Miguel are founded on durable rock of such excellent character that a part of it will be left in place to form the separating wall between the lock chambers. The excavation for the locks is practically complete The West dam is being constructed of rock and earth with puddled clay as a center and the material underlying the dam is impervious At Miraflores about one-half of the excavation for the lock has been completed, and the general plans for the dams have been approved

Excellent progress has been made on the entrance channel on the Pacific, from which during the year 8,475 931 cubic yards was removed The channel has been carried to full depth for about five miles from deep water

Due mainly to the great increase in the dimensions both of the prism of the canal and of the locks, and to the higher cost of labor and materials, the estimate of the total cost of the completed work shows an increase over the original estimate of nearly fifty per cent. The total cost of engineering and construction will be $297 766,000 and if the purchase price and the cost of sanitation and civil government be added, the total final cost will be brought up to $375 201,000

THE TRIALS OF THE BATTLESHIP "NORTH DAKOTA"

The government acceptance trials of the battleship "North Dakota," of which we gave a preliminary account in our issue of November 13th, have now been successfully completed, with results which are gratifying alike to the Navy Department and the builders of the ship

When the question of installing turbines in place of reciprocating engines in the new warships of our navy first came up for discussion the attitude of the Bureau of Steam Engineering was decidedly conservative. The Department felt that sufficient experience was not available with the turbine at least under battleship conditions to warrant its immediate adoption at the time it was proposed Ultimately, however it was decided to install the Curtis turbine in one of the two battleships authorized by Congress in March 1907 and to equip the sister ship with standard marine reciprocating engines.

Now that the trials both of the "Delaware" and the "North Dakota" have been completed it is possible to make a reliable comparison of the two types of engine, and it is gratifying to know that on every point of comparison except those of water consumption and propeller efficiency, the turbine has shown its superiority In the standardization trial the "North Dakota" ran her fastest mile at a speed of 22 25 knots, and made an average speed for the five runs of 21.83 knots. She showed a maximum horse-power for one mile of 35,150 In these trials she exceeded the mean speed of the "Delaware" by 0 39 knot, and her turbines developed over 5,000 more horse-power The results of the three hours' full-power trial, and the runs for twenty four hours respectively at 19 knots and 12 knots, as herewith given, are highly satisfactory Aside from the fact that she attained a full-power speed of 21.64 knots against the contract requirement of 21 knots the most satisfactory feature is the remarkably low coal consumption of the ship, particularly at low speed—for one of the most serious charges formerly made against the turbine was that of its extravagance in coal consumption under low-speed conditions. The coal per horse-power per hour for the total horse-power worked out at 1.68 pounds at full speed; at 19 knots speed it was 1.58 pounds and at 12 knots it was 2 34 pounds. The coal per horse-power per hour of an equivalent indicated horse-power (the power was taken by torsionmeter from the propeller shaft) works out for the three speeds, respectively, at 1.55, 1.46, and 2.15 pounds per horse-power per hour With the ship at her maximum displacement, the steaming radius of the "North Dakota" would therefore be 3,000 knots at 21½ knots, 4,600 knots at 19 knots, and 9,000 knots at 12 knots speed. Compared with the reciprocating-engine-driven "Delaware," the turbine-driven "North Dakota" required only 295 as against 315 tons of coal per twenty-four hours on the 19-knot trial, and 105 as against 111 tons on the 12-knot trial.

OFFICIAL TRIALS OF THE "NORTH DAKOTA."

	3 hours of full power trial.	24-hour trial at 19 knots.	24-hour trial at 12 knots.

24 hour 19 knot trial	16 1	15 29	5.0
24 hour 12 knot trial	23 2	22.3	3.0

The "North Dakota" is driven by two Curtis turbines the pitch diameter of whose moving buckets is 144 inches. There are nine stages for going ahead and two for going astern The shaft diameter is 30 inches, and the bearings at each end of the turbine are 21 inches in diameter by 42 inches long. The steam, superheated fifty degrees enters the steam chest at a pressure of 280 pounds absolute. Here it passes through twenty nozzles, where it is expanded and acquires a velocity of 3,000 feet per second, its pressure falling to 75 pounds absolute It then passes through another set of nozzles between the first and second stage, where it acquires a velocity of 1,070 feet per second leaving the blades with a velocity of 155 feet per second. The pressure in the second stage is 49 4 pounds absolute From the second to the eighth stage the entrance velocity of the steam remains at 1,070 feet per second, and the exit velocity at 155 feet per second. The pressure, however, drops from 75 pounds in the first stage to one pound absolute in the ninth stage, at which pressure it passes to the condenser, where a vacuum of 28½ inches is maintained It can thus be seen that as the steam traverses the successive stages there is a continual drop in pressure, the energy of the steam being delivered to the moving blades in the form of impact, the velocity of which is developed by expanding the steam in series of nozzles forming the entrance to each stage. The number of nozzles increases from 20 in the first stage to 360 at the sixth stage The buckets in the first stage are 1¼ inches in length and they increase to a length of 12 inches in the last stage.

In the two stages of the reverse turbine, it has proved possible to develop about 60 per cent of the power that can be developed on the go-ahead turbines, and thus the objection which has been raised against the turbine that it provides insufficient maneuvering power may be considered to be pretty well met. In this connection it may be mentioned that in the trials of the Japanese cruiser "Ibuki," which is equipped with turbines of this type, when the ship was steaming at 20 knots, it was possible in reversing to stop the starboard turbine in 22 seconds, the port turbine in 25 seconds, and bring the vessel to absolute rest in two minutes.

* * *

The ancient Romans commonly wrote with a metal point (stylus) on wooden tablets covered with wax (tabulae), but permanent records were written on parchment with a reed pen and liquid pigment, or ink. At Haltern in Westphalia, near the site of the Aliso fortress erected by Drusus in the year 11 B. C., was recently found a bronze vessel containing a dried black mass, which Prof. Kassner has decided to be Roman ink The mass was found to consist chiefly of soot and tannate of iron. It also contained smaller quantities of ferric oxide, copper oxide, clay, magnesia, gypsum, phosphoric acid, carbonic acid, alkalies, and sand. These ingredients probably represent chiefly accidental impurities which have found their way into the old inkstand, but some of them may be due to the chemical action of the ink on the bronze vessel. The presence of an aromatic substance suggests that the ink was imported from Italy, where the use of perfumed ink was common.

[illegible] at the [illegible] for sale. The decorations [illegible], and the exhibition was [illegible].

[illegible] electric railway in Norway has [illegible] connecting Thamshaven and Lökken [illegible] current from a hydraulic generating [illegible] Thamshaven, which generates three-phase current at [illegible] volts. This is converted into [illegible] current of 6,600 volts for use on the electric railway. The line was built for the purpose of [illegible] deposits in the region and for the convenience of tourists.

A [illegible] electric arc lamp has recently been designed, in which the carbons are formed out of plastic material in the lamp itself. The lamp is provided with the receptacles in which the plastic material is placed, and this is fed through tubes to form the two electrodes of the arc. The ends of the electrodes are baked by means of electric heating coils, and the process is a continuous one. The gas generated as the material is heated is utilized to press the material into the electrode-forming tubes.

It is customary in Europe to place a netting under high-tension lines at railroads and important street crossings. As a further protection at such points, an inventor has recently devised a safety suspension in which the line is divided into three parts at the crossings and supported on three insulators, any one of which will bear the entire weight of the line at that point in case the others should be fused or broken. The German Post Office Department has approved of this system, and permits its use at crossings.

Governor's Island, New York, is to be provided with an electric fire-fighting plant. Heretofore there has been no apparatus for fighting fire except that carried by the small ferryboat that plies between the island and the Battery. Not long ago a fire took place while the boat was on its way to Manhattan, and before its return much damage was done. This demonstrated the necessity of providing the island with a fire engine of its own. The equipment that is to be installed consists of a turbine pump throwing a four-inch stream and operated by an electric motor.

The Canadian government has been petitioned to allow a Canadian power company to build a dam across the St. Lawrence River near Cornwall. This concern is associated with an American company. It is their plan to dam the South Sault channel at first, to obtain 65,000 to 70,000 horse-power. Later it is expected that a dam will be built across the main channel. This dam would not interfere with the Cornwall Canal. However, the plans provide for the building of a lock, through which at a single lift of 40 feet vessels could pass the rapids.

The work of extending the electric zone of the New York Central Railroad as far as North White Plains is proceeding quite rapidly, and it is expected that by the first of the year it will be in full operation. The temporary terminal at Wakefield, where steam and electric locomotives are interchanged, will then be abandoned. A new sub-station is being erected at Tuckahoe, and another one at White Plains. Each will be equipped with three 1,000-kilowatt rotary converters and nine single-phase transformers of 375 kilowatts capacity each.

Working on the theory that earthquakes are preceded by an electro-magnetic disturbance, an Italian scientist has devised an instrument which gives warning that an earthquake is about to occur a few minutes before the disturbance is felt. With this instrument the inventor, Padre [illegible], received warning of two earthquake shocks that occurred about ten miles from his laboratory four minutes before the earth waves affected the seismograph. The instrument is connected to a clock, and is so arranged as to record the time elapsing between the arrival of the electro-magnetic wave and the seismic waves.

[illegible] fact that a [illegible]. In order to overcome [illegible], a German inventor has devised an [illegible] which produces [illegible] and very [illegible] to take up [illegible]. The [illegible] is produced by [illegible]

[illegible]

The United States Geological Survey reports that in 1908 California produced $19,761,859 in gold, 1,447,273 ounces of silver valued at $873,057, and 706 ounces of refined platinum valued at $12,414. This platinum was all produced at placer mines in Butte, Humboldt, Siskiyou, Trinity, Calaveras, Sacramento, and Del Norte counties, three-fourths of it having been mined in Butte County.

On the suggestion of Prof. Tissot, of France, an international commission has been organized for the purpose of transmitting wireless time signals from stations suitably located on coasts and islands to vessels navigating all waters. The establishment of this system would make the determination of longitude at sea very accurate and independent of the errors of the chronometer, which, indeed, would become superfluous. For transmitting the time signals Tissot recommends the wave length of 1,800 meters, or about 5,900 feet, which is used at the Eiffel tower station.

Eusapia Paladino, the Italian spiritualistic medium, who recently arrived in this country, has given some evidence of her powers. The phenomena of her first séances were the familiar physical phenomena of spiritualism. That is, they consisted of table rappings and levitations. Although considerable skepticism prevails as to the honesty of the medium, it must be admitted that she has not been latterly detected in fraud. Many years ago she was caught in petty tricks, which have by no means thrown her into discredit, because they seemed to have been due to involuntary actions in the trance condition. Whether or not her more recent performances are genuine, we are not prepared to state. Certain it is, that her performances should be studied with scientific care.

Last year a small lot of shelled corn of a kind new to this country was sent to the Department of Agriculture from Shanghai. It proved to have qualities that may make it valuable in breeding a corn adapted to the hot and dry conditions of the Southwest. The plants raised in the test averaged less than six feet in height, with an average of twelve green leaves at the time of tasseling. The ears averaged 5½ inches in length and 4 1/3 inches in greatest circumference, with sixteen to eighteen rows of small grains. On the upper part of the plant the leaves are all on one side of the stalk, instead of being arranged in two rows on opposite sides. Besides this, the upper leaves stand erect instead of drooping, and the tips of the leaves are therefore above the top of the tassel. The silks of the ear are produced at the point where the leaf blade is joined to the leaf sheath, and they appear before there is any sign of an ear except a slight swelling.

It is not an uncommon thing for corrosion and oxidation of bright steel objects to be caused by the presence of injurious substances in paper. This may be due either to free acids or chlorine compounds, or more frequently, especially in the case of hard-sized paper, to the excessive use of aluminium sulphate, which is gradually dissociated by atmospheric influences. Another drawback associated with certain kinds of paper is the blackening (due to formation of sulphide) which it produces on articles of silver or copper. Owing to the growing use of paper of wood pulp prepared by digestion with sulphur compounds this blackening action is more prevalent now than formerly. In fact, it is asserted by Herr Klemm in a recent investigation of this subject, that most, if not all, unbleached wood pulps of the sulphite and sulphate class contain traces of sulphur compounds that have a blackening action upon silver or copper, and that even bleached pulps may contain minute quantities of similar substances. Unbleached pulps prepared by the caustic soda process and mechanical wood pulps, however, are generally free from these sulphur compounds.

Capt. Roald Amundsen, the discoverer of the Northwest Passage, arrived in the United States recently. Capt. Amundsen has come here to make preparations for his expedition to the Arctic which he calculated would keep him away from civilization probably more than five years. His primary object will be to explore the ocean depths of the region, to study the currents and temperatures and the character of the ocean bottoms. He will start from San Francisco in July, 1911, in the 400-ton gasoline auxiliary schooner "Fram," which was used by Nansen in his trip to the North. The Norwegian government has put up $20,000 for the expedition and there have been many private subscriptions from well-to-do Scandinavians interested in polar exploration and desirous of having their own people win the glory of discovery. Capt. Amundsen says his calculations in regard to the drift of the "Gjoa" were verified by events, and that he believes that the "Fram" will take the course that he is confident the drift will force her to take. He can assist in making that course [illegible] nearly across the pole by the use of his gasoline engine at periods when the pack will [illegible]

AERONAUTICS.

On October 23d, M. Bleriot made two flights with his monoplane of [illegible] and 17 minutes' duration at Vienna. After the first flight he was presented to the Austrian Emperor, who was greatly interested in his machine. From Vienna M. Bleriot went to Bucharest, and made some flights before the King of Roumania.

Recognizing that in order to see flights by the daring French aviators substantial cash inducements must be offered, the people of Los Angeles, Cal., have raised $50,000 for prizes to be competed for by leading aviators of France and America at an aviation meeting to be held on the Pacific coast in January. Paulhan, Delagrange, and several other of the French aviators have agreed to compete, according to cable dispatches.

Before leaving New York for their home in Dayton, Ohio, a few days ago, Orville and Wilbur Wright entered the French consul's office in New York late one afternoon and received from France's representative crosses and diplomas of the Legion of Honor. Not until several days later did Miss Katharine Wright accidentally discover in one of her elder brother's pockets the decoration that is so much prized and sought after by distinguished men here and abroad. So engrossed was he in business relative to his aeroplanes that he had forgotten to mention it to his sister.

The flying of model aeroplanes for prizes, which has been done almost weekly for some time past at the meetings of the Aeronautic Society, has been taken up by quite a number of boys in New York city, who have made some excellent records at this interesting and instructive sport. Contests are held weekly under the auspices of the West Side Y. M. C. A., where Wilbur R. Kimball, E.E., is giving a course of lectures upon aeronautics. Cups have been given as prizes by Mr. Louis R. Adams and by Mr. Wilson Marshall, whose 12-year-old son, Wilson Marshall, Jr., has won two legs of the Adams trophy with a biplane model of the Wright type. Propelled by a rubber band motor, this model, the planes of which are about 2 feet long, covered 64 feet 9 inches in its longest flight.

Although Farman and Paulhan have quite frequently taken their wives on flights in their Farman biplanes, neither of these ladies has essayed to fly alone. It has remained for the Baroness de la Roche to become the first aviatress. After receiving several lessons from M. Chateau, the instructor employed by the Voisin Frères at Chalons, the Baroness made a short initial flight of about 300 yards. The following day this titled lady flew twice around the parade ground—a distance of about 4 miles—in a rather gusty wind. After the first few turns she was able to fly the machine without any trouble whatever, and seemed to have the biplane under perfect control. This flight gave a good demonstration of fairly good automatic stability secured in the Voisin machine by the use of vertical partitions between the main surfaces and in the tail. In America a Curtiss biplane is reported to have been sold to a wealthy lady in Florida.

The "Parseval III." airship, which has been at the Frankfort Aeronautical Exposition the past summer, made a grand tour above south Germany from October 12th to 16th, in the course of which it passed over Nuremberg, Augsburg, München, and Stuttgart. The 135 kilometers (83.8 miles) from Nuremberg to Augsburg *via* Treuchtlingen, Mannheim, and Donauwörth was covered in 3¾ hours at an average speed of 22 1-3 miles an hour. On the return journey in a straight line on October 14th, however, the airship is said to have covered about 37 miles in an hour. This very much greater speed on the return journey was perhaps due to more favorable conditions and to the forcing of the airship at its limit of speed throughout the shorter distance. That its speed is superior to that of the "Zeppelin" has been testified to by a well known American aviator who took a trip in the latter last summer and said that the "Parseval" readily passed it, although the "Zeppelin" airship made but 25 miles an hour according to his timing.

Herr Hans Grade, the first German aviator to fly successfully with a monoplane of his own invention, and whose machine was shown in flight in our issue of October 23rd, has at last won the Lanz prize of $10,000 for the first kilometer flight by a German-built and piloted aeroplane. After first performing the required flight in 3 minutes 21 seconds above the Mars field at Bork on October 17th (besides which he made three other flights of 6 minutes 20 seconds, 48 seconds, and 2 minutes 20 seconds on the same day), Herr Grade took his monoplane to the aviation field at Johannisthal (where the flight for the prize was required to be made) and won the prize in short order on the 30th ultimo. The following day he made three flights of 3¾, 14¼, and 5 minutes' duration respectively, and a fourth flight in which he made one circuit of the field. The motor used by Herr Grade is a 4-cylinder, V-type, air-cooled motor of his own invention which develops 24 horse-power and weighs 77 pounds. It makes 1,200 to 1,400 revolutions per minute and carries the propeller upon its crankshaft.

SALVAGE OF THE UNITED STATES CRUISER "YANKEE" BY COMPRESSED AIR.

The present attempt to raise the United States auxiliary cruiser Yankee is the first application to a United States warship of the method of salvage by compressed air used by Mr John Arbuckle The system has already proved its efficiency in the case of the raising of the steamship Bavarian of 12 000 tons after she had run upon the rocks in the St Lawrence River

In both the old system and the new the raising of a sunken vessel is accomplished by removing sufficient water from the hull of the ship to give the necessary buoyancy for flotation Under both methods the space within the ship that is rid of this water is filled with air but there is this important difference that under the ordinary method the air is at atmospheric pressure whereas under the Arbuckle method it is under a pressure equal to the depth of the hold or compartment from which the water is driven out

In raising ships it has been customary to send down divers who by means of patches of plating plugs wooden caissons cement etc attempted to patch up the hole in the hull and render the ship fairly tight When these repairs had been completed powerful pumps were installed upon the ship or upon wrecking vessels moored alongside and sufficient water was pumped out to lift the ship off the rocks and enable her to be towed to the nearest drydock

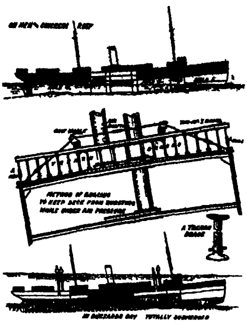
It frequently happened however that the perforations of the hull were so many or of such extent sometimes large portions of the bottom being torn entirely away that salvage by the pumping method was practically impossible This was due largely to the fact that the patchwork—plugs canvas cement and whatnot—was exposed to an inward pressure corresponding to the depth of the injured portion of the ship below water which pressure was so great as to exceed the resisting strength of the temporary repairs.

It ocurred to Arbuckle a few years ago that there was no reason why the compressed air method as used in driving tunnels below the East and Hudson rivers should not prove effective in the salvage of sunken ships for if the mud silt and water can be held from entering the open end of a tunnel by opposing against it an air pressure equal to the water pressure at that level it seemed probable that the water could be expelled through the perforated bottom of a ship and held permanently at the level of this perforation by the same use of compressed air

Although it necessitates some exceedingly difficult engineering work and the exercise of considerable ingenuity the method by which the compressed air is used for freeing the ship of water is simple and easily understood No attempt is made to close the perforations in the bottom of the hull but great care is taken to render airtight the sides and roof of the various holds and compartments Air-supply pipes are led into the various compartments and compressed air is forced in and the water gradually expelled through the bottom until the level of the water in the various holds has been driven down to the highest point at which the hull has been perforated It is evident that as long as the air pressure is maintained the water cannot re-enter By estimating the capacity of the compartments thus treated and knowing the weight of the vessel it is possible to free the ship of the exact amount of water to bring her to the surface and make her float at some predetermined draft

The Yankee is one of four merchant ships built between 1890 and 1892 which were purchased during the war with Spain and transformed into auxiliary cruisers Latterly she has served as a torpedo supply ship She is 492 feet long 48 feet 4 inches in breadth and draws 20 feet of water on a displacement of 6 225 tons

In the autumn of 1908 she was run upon the Hen and Chickens Reef at the entrance to Buzzard's Bay and badly wrecked holds 1 2 3 and 4 being badly perforated as shown in the accompanying diagram. The Navy Department endeavored to float the ship by the customary method of closing the holds and pumping, but failing to get her off they abandoned their efforts and called for bids by private wrecking companies. The condition of the ship was generally considered to be hopeless and John Arbuckle was the only bidder Operations were commenced on October [illegible], 1908. The berth deck throughout the whole length of the ship was made thoroughly watertight, and the water was driven out of holds 1, 2, 3, and 4 by compressed air, the engine and boiler rooms being emptied by pumping. The vessel was floated after forty five days of operations, and was being towed into New Bedford when, unfortunately the weather became very boisterous and a tug in going alongside the "Yankee" was driven against the portholes of the room containing the air-compressing machinery and



METHOD OF BRACING TO KEEP DECK FROM BURSTING UNDER AIR PRESSURE
A TRUSSED BRACE
IN BUZZARDS BAY TOTALLY SUBMERGED

In the two diagrams of the Yankee the portions of the ship from which the water was expelled are shown in white

RAISING THE YANKEE BY COMPRESSED AIR

stove them in and the water flooded the compartment and stopped the compressors The vessel slowly sank at a point one mile east of the Dumplings in Buzzard's Bay at the entrance to New Bedford Harbor and lay in the position shown in our various engravings The bow of the vessel was a few feet below the water but the stern lay thirty feet below the surface

In the new salvage operations it was decided to leave the lower holds the engine and boiler rooms and the greater part of the gun deck full of water and lift the ship by expelling the water from the upper portion of hold No 1 from the whole of the berth deck and from the after portion of the gun deck Reference to the engravings will explain the conditions of flotation the unwatered areas being shown in white The first step was to make special steel hatches fasten them securely in place and calk them thoroughly watertight The gun deck being of steel was sufficiently watertight in itself but the after portion of the spar deck being of wood and having comparatively little resisting strength against the upward pressure of the air it became necessary to reinforce it strongly This was done by placing above the spar deck and upon the deck house a series of 10-inch I beams arranged in pairs, which extended the full width of the vessel. At its outer ends each pair of beams was anchored down to the waterway at the side of the ship by 2-inch iron rods set up with turnbuckles. Upon the beams immediately over the side walls of the deck house, two 12 x 12 timbers were placed parallel with the axis of the ship. Upon the outer [illegible] of these beams were set special cast-iron angle blocks, which [illegible] each [illegible] of 13-inch trusses [illegible] to eyebolts which passed through the [illegible] the ship and were held in place by nuts. [illegible] under side of the I beam and the spar deck was [illegible] a number of trench braces which were set up [illegible] they bore snugly against the spar deck, thereby helping to transfer the upward pressure of the air to the system of trussed I beams as above described.

The special steel hatches were provided with openings to which were coupled five large steel airshafts, which extended above the surface of the water and were provided at their upper ends with air locks. The wrecking plant consists of a large schooner which is fitted up with living accommodations for the men; a big wrecking steamer upon which is installed a compressor plant capable of delivering 5,000 cubic feet of free air per minute a number of ship's boats, and a steam tug which makes regular trips between New Bedford and the scene of the wreck two miles out in Buzzard's Bay The difficulties of the work are greatly enhanced by the exposed position of the wreck, and there are necessarily many days when it is impossible to do any work.

These remarkable salvage operations have made excellent progress The sections of the ship to be unwatered have been made airtight the truss bridging over the spar deck is completed and it is expected that very shortly as soon as a favorable conjunction of wind and tides is presented the "Yankee" will be brought to the surface and towed into drydock Considering the great depth of water in which the ship lies her salvage will be one of the most remarkable feats of its kind in the history of wrecking operations.

A GASOLINE ENGINE FOR CORN HUSKING.

BY FRANK C PERKINS

At slight expense by the development of the gasoline motor the farmer is now enabled with modern labor-saving devices to do many times the amount of work formerly possible. The accompanying illustration shows the use of a small portable gasoline engine mounted on a simple four wheeled truck in operation just outside of the barn driving a corn husker by belt transmission

Thousands of acres of corn are not cut up but husked from the stalk thus entailing an entire loss except for the fertilising value and a small amount of feed

With a motor-driven husker located at the barn it is a simple matter to "jerk" the stalk corn, a process which is speedier than husking and to shovel it into the machine by which the ears are husked The husks are blown to the mow or barge made of wire fencing They can afterward be baled and sold at a good price to mattress manufacturers the husk alone netting a good profit while the feeding or fertilising value of the stalks is not materially lessened

For operating the husking machine only a four to six horse-power gasoline engine is required while it is stated that hundreds of bushels of corn have been husked by a machine of this type with only a three-horse-power engine under favorable conditions. In central Ohio a four roll machine has been able to husk 250 bushels in a day requiring four teams and one extra man besides the three men that operate the machine with a cash outlay of twenty five dollars per day It is stated that one of these small husking machines operated by a light gasoline engine will handle the same 250 bushels at less than half the expense or $11 50 This motor-driven husker is of the two-roll type, the rolls being four feet in length and large in diameter It runs at high speed, thereby greatly increasing the capacity, which is about 10 bushels per hour under normal conditions but has been operated at over 16 bushels without difficulty It is stated that the average run is from 7 to 10 shocks (12 hills square) per hour.

A GASOLINE ENGINE FOR CORN HUSKING.

The shredder head is composed of knives strung on a shaft 13/16 inch in diameter, held in position so that only one knife strikes at a time. The knives strike with a shear cut each [illegible] inches on the stalk, leaving the blades in good condition.

The blower is arranged at the rear of the shredder so that all the stover must pass over the [illegible] [illegible]

[illegible] for switching the [illegible] to the machine [illegible] power is developed as well as the [illegible] movement of a lever attached to a [illegible]

THE GYROSCOPIC MONO-RAILROAD

In the spring of 1907, Mr. Louis Brennan, inventor of the Brennan torpedo, exhibited before the Royal Society of England a small car which traveled on a single rail or cableway, and kept its equilibrium perfectly even while rounding curves and when its load was shifted from one side to the other. This feat, an apparent defiance of the laws of gravity, aroused a great deal of interest, and it was predicted that it marked a revolution in railroad practice. The car was kept in equilibrium by means of a pair of wheels, that were rotated at high speed in opposite directions. The gyroscopic effect of these rotating masses prevented the car from toppling over, in the same way that a top is kept from falling while spinning at high speed. Since the first exhibition of the gyroscopic car, Mr Brennan has been at work developing details, which would permit of using the same principle on a much larger car suitable for carrying heavy loads. A couple of weeks ago Mr Brennan's invention, now reduced to practical dimensions, was again exhibited before the Royal Society. The car was 14 feet long, 13 feet high, and 10 feet wide, weighing 22 tons. Carrying a load of 40 passengers, the car traveled on a single rail around a circular track 220 yards in circumference. The balance was perfectly kept by means of two gyroscopes weighing three-quarters of a ton each and revolving at a speed of 3,000 revolutions per minute. The wheels were incased and ran in a vacuum, so as to reduce friction to a minimum. A gasoline engine was used, to keep the gyroscopes spinning and also to propel the car. The car was subjected to the severest of tests, the passengers suddenly shifting from one side to the other in their endeavor to destroy the equilibrium, but the gyroscope wheels responded to the slightest disturbance, and restored the balance at once. One of the difficulties encountered in a car of this type is the precessional action accompanying the gyroscopic motion. This, however, was overcome by means of friction devices. The advantage of using a monorail is that the cost of construction is considerably less, but in addition to this there is the fact that a slight deviation from a true line would result in no damage, whereas when two parallel tracks are used they must both be kept perfectly parallel and in perfect alignment, otherwise the car will run off the track or will rock violently if one side dips below the other. In other words, a double-rail track is more difficult to keep in repair than two monorails, for the reason that the two rails are interdependent, and variation in one must not take place without a corresponding variation in the other. In rounding curves there is always danger of spreading the tracks where a double-rail track is used, while with the monorail line, should the side thrust be sufficient to shift the rail, there would be no tendency for the car wheels to leave the track. As yet the details of Mr. Brennan's invention have not been [illegible]

THE GYROSCOPIC MONO-RAILROAD.

The Chemistry of Soldering Agents.

BY A. LIPPMANN.

The following summarizes the results of two years' practical experiments with soldering agents, chiefly those of the "soft" type which are suitable for electrical work, where it is necessary for the security of the service to keep within definite limits the resistance introduced and the heat generated at the points of junction. The requirements of mechanical strength, however, demand that the surfaces of contact of the wires shall be sufficiently extended to satisfy the condition of low electrical resistance, and when we consider that ordinary tin and lead solder has a specific resistance 10 or 12 times that of copper, it becomes evident that the chief function of the solder is not to conduct electricity but to protect and maintain the contacts of wire, and to preserve the copper surfaces from oxidation.

There is a traditional belief that hydrochloric acid and other acid soldering liquids should not be used in electrical work, because acid left on the joint by a careless workman may, especially during the passage of a current, give rise to secondary electrolytic actions which will in time destroy the connection. Investigation of many imperfectly soldered joints, however, has failed to indicate any injurious effect due to acids, and has revealed causes of very different character. In most cases of large wires traversed by strong currents, insufficient contact had caused overheating of the joint and fusion of the solder. In some instances the trouble was attributable to the formation of electric arcs between wires which were not held closely together by the solder.

No injury due to the employment of acids could be detected even in resistance coils. With the fine wire used in these coils injuries are far more likely to be caused by careless handling (overheating or burning during the operation of soldering) than by acids.

These considerations lead me to form a lower estimate of the injurious action of acid soldering liquids than is commonly entertained. The investigation in question was undertaken primarily to settle a dispute concerning the relative safety of two soldering liquids, of which one contained ammonium chloride and the other zinc chloride. The difficulty of deciding the question had been increased by the circumstance that an injurious action had been attributed to the hydrochloric acid contained in both soldering agents.

The first requirement for making a good connection by soldering is the presence of absolutely clean metal surfaces. If diluted hydrochloric acid is employed as a soldering liquid a good connection can be made between surfaces not originally quite clean. Many coppersmiths use dilute hydrochloric acid exclusively in fine art work. Experience shows that no injurious after effect need be feared if the soldered joints are well washed with water. The notion that hydrochloric acid is difficult to remove is disproved by the great volatility of the acid. Ammonium chloride (sal ammoniac) is inferior as a flux to hydrochloric acid, and also to zinc chloride and zinc ammonium chloride.

I made experiments in soldering with a preparation of ammonium chloride, to which ammonia was added drop by drop. The efficiency of the soldering liquid visibly diminished as the proportion of ammonia increased. Soda lye, added to neutralization, made the liquid entirely unfit for use. Hence I attributed the good effect of ammonium chloride to the hydrochloric acid which is gradually separated in the operation of soldering. Experiment showed, however, that ammonium chloride does exert an injurious action on copper. When a mixture of ammonium chloride solution with glycerin was employed in soldering heavy copper cables to each other or to sockets, it was found almost impossible to prevent the liquid from penetrating between the wires of the cable. I examined many such joints two weeks, three weeks, and six months after soldering. In two weeks the wires of the core had become covered with a thick green coating of copper salt. I at first attributed the formation of this salt exclusively to the action of free hydrochloric acid, but Samter has shown that ammonium salts possess a remarkable power of forming complex combinations with copper.

Zinc chloride, zinc ammonium chloride and soldering soaps containing these salts may be regarded as the standard soldering agents. Zinc

(Concluded on page 390)

Census of Dirigibles and Aeroplanes.

The well known explorer and sportsman, the Prince Scipio Borghese, has presented to the Chamber of Deputies of Italy a tabulated statement showing the number of dirigibles and aeroplanes in existence in the world on September 30th. The former number 36; the latter, 76. In addition, 68 dirigibles are in course of construction. The number of machines first cited are divided among the different countries as follows:

	Dirigibles.	Aeroplanes.
France	9	27
United States	7	17
Germany	10	6
England	2	6
Belgium	1	5
Italy	3	2
Austria		5
Japan	1	3
Russia	2	1
Switzerland		2
Spain		2

The dirigibles are divided as follows into military and private ones.

	Military	Private.
Germany	7	2
France	4	5
United States	2	5
England	2	1
Italy	1	2
Russia	2	
Belgium		1
Japan	1	

The census of dirigibles under construction is as follows:

	Military	Private.
Germany	8	7
France	5	10
United States	4	7
England	4	1
Italy	2	3
Russia	4	
Japan	2	1
Belgium	1	2
Austria	1	2
Spain	2	
Switzerland	1	1

The number of aeroplanes which are known to exist are parceled among the different nations as follows:

France	27	Japan	3
United States	17	Switzerland	2
Germany	6	Italy	2
England	6	Spain	2
Austria	5	Russia	1
Belgium	5		

France, which possesses more than one-third of the aeroplanes in existence, is therefore considerably farther advanced than the other nations in this respect.

◆

The Life of the Infinitely Small.

A few years ago Prof. Metchnikoff ingeniously projected upon the screen the struggle of the red and the white corpuscles in the blood. The spectacle was highly entertaining, but unfortunately lasted but a few seconds, for which reason the application of the process was exceedingly limited.

Thanks to a new apparatus recently devised by Dr. Comandon, and exhibited before the Academy of Sciences by Prof. Dastre, the moving picture machine is made to give an enlarged view of the small microbes in activity. Briefly stated, Comandon has devised a method of employing the ultramicroscope for the purpose of photographing microscopic life on a moving picture film.

The ultramicroscope, which has been more than once described in the columns of the SCIENTIFIC AMERICAN SUPPLEMENT, is not essentially different from any other microscope, except in the method of lighting the object to be utilized. In an ordinary microscope the light passes through a glass plate which supports the object, and thence travels to the eyepiece. Infinitely small objects are literally drowned in this brilliancy, and are therefore invisible. Their luminous intensity is not sufficiently different from that of the ambient light. With such an ordinary microscope it is impossible to study objects smaller in diameter than one-half a micron—a micron being equal to the thousandth part of a millimeter. The ultramicroscope comprises the same arrangement of lenses as an ordinary microscope. Instead of illuminating the object from below and normally to the plane of the stage, the object is illuminated from the side or obliquely, so that the light rays fall only on the slightly elevated object, and therefore leave everything else in obscurity. This result is obtained by a simple system of prisms and lenses.

Without entering into technical details, it may be said that with an ordinary microscope the eye is transported into a chamber bathed with sunlight. With the ultramicroscope the eye is transported to a dark room traversed by a single ray of light, so that it renders visible dust particles which otherwise would be invisible if the room were regularly illuminated. Hence the ultramicroscope renders it possible to distinguish microscopic objects measuring not more than 1/100th of a micron in diameter, or 1/100,000th of a millimeter.

Comandon has succeeded in combining the ultramicroscope with the [illegible] to register upon a photographic film the life history of many infinitely small microbes. Among the many interesting films which were thrown upon the screen during Dr. Dastre's discourse before the Academy was one showing the struggles of the white and the red corpuscles in the blood. The red corpuscles appeared as black globules outlined with white, and the white corpuscles appeared as white splashes. The picture of the corpuscles filed past at the rate of 960 a minute, each having been taken in about 1/32nd part of a second. The moving picture film views appeared on the screen magnified from 10,000 to 20,000 diameters. An inch seen under these conditions would seem about as high as a six-story house. The ultramicroscope moving-picture machine will undoubtedly render excellent service in biology, because it will register certain phenomena which at present cannot be studied.

It may be stated without in the least detracting from the work of Dr. Comandon that similar results have been already obtained by an English naturalist, Mr. Mark Duncan. Furthermore, Mlle. Cheroton (the collaborator of Prof. Franck of the College de France) and M. Vlès have also chromophotographically studied the segmentation of sea urchins' eggs in the biological laboratory of Roscoff.

Pseudo Blood Oranges.

It sometimes happens that a physician leaves absentmindedly in the tissues of his patient one of those fine needles which terminate the Pravaz syringe, be it by some wrong manipulation, or because of some awkward movement by the patient.

In such a case the treatment is very simple. One simply says nothing about it, and the patient does not notice it. The accident is of no consequence, the needle is not absorbed—of this there is no doubt—but proceeds leisurely through the tissues to some other point of the body.

Unfortunately it is not so much that trouble may arise by this behavior of Pravaz needles, and that pain may be caused thereby, as it is that they may be brought about *secundum artem*. We find an example in the Presse Medicale.

Blood oranges are often, it appears, "faked," at least in northern climes, where they command a higher price than the ordinary orange.

In order to transform these latter into blood oranges, certain "manufacturers" inject into the orange, through the rind, with the aid of a syringe provided with a fine needle, a solution of red aniline dye mixed with a saccharine solution. Now, recently, in St. Petersburg, a lady bought from a fruit merchant a dozen of these pseudo blood oranges. She gave one to her little daughter, but was distracted to find on putting the first piece into her mouth that she was attacked by a sharp pain in the region of the pharynx and spat blood. A physician being hurriedly called diagnosed the pain and hemorrhage as having been caused by a fragment of a needle which had lodged in the mucous membrane of the pharynx. When this fragment was extracted it proved to be a point of a Pravaz needle, in the eye of which was found a small remaining portion of aniline color.

On returning to the orange dealer, he revealed that the "dodge" is often resorted to in manufacturing blood oranges.—Cosmos.

Wireless Telegraphy in the Antarctic.

The new expedition which is being fitted out in England to go to the South Pole, it is proposed to maintain in communication with the civilized world during the entire course of its exploration. Wireless telegraph apparatus will be installed on the [illegible] the ship of the expedition, which will serve as a base, and other apparatus will be carried by the different exploring parties, so that they can remain always in communication, more or less directly, with New Zealand.

[illegible] Pitchblende, [illegible] as an ore of radium, occurs in [illegible] States only in Gilpin County, Colo., [illegible] four mines that produce it. Carnotite [illegible] bright yellow powder in sandstones [illegible] rado.

Uranium minerals are radioactive, and [illegible] activity may be tested by their effect upon a photographic plate, which will show shadows of [illegible] objects placed between it and a specimen of [illegible] mineral.

Uranium has not yet been put to many practical uses. It is said to be used in steel making in Germany. Uranium salts are used in iridescent glass and in pottery glazes, and uranium compounds are employed in chemistry and in medicine. A number of the uranium salts are violent poisons. Uranium and uranium salts were imported into the United States in 1908 to the value of $7,148, according to F. L. Hess, of the United States Geological Survey, whose report on uranium and other rare metals is published by the Survey as an advance chapter from "Mineral Resources of the United States, calendar year 1908."

◆

Serviceability and Cleanliness of Alcohol.

Where the restrictions placed on the use of denatured alcohol are less stringent than those placed on the use of gasoline, or where safety and cleanliness are important requisites, the advantages to be gained by the use of alcohol engines in place of gasoline engines may overbalance a considerable increase in the fuel expense, especially if the cost of fuel is but a small portion of the total expense involved. Denatured alcohol will, however, probably not be much used for power purposes until it becomes as cheap as gasoline and until the equality of gasoline and alcohol engines in respect to adaptability to service required and quantity of fuel consumed per brake horse-power becomes more generally realized.

In regard to general cleanliness, such as absence of smoke and disagreeable odor, alcohol has many advantages over gasoline or kerosene as a fuel. The exhaust from an alcohol engine is never clouded with black or grayish smoke, as is the exhaust of a gasoline or kerosene engine when the combustion of the fuel is incomplete, and it is seldom, if ever, clouded with bluish smoke when a cylinder oil of too low a fire test is used or an excessive amount supplied. The odor of denatured alcohol and the exhaust gases from an alcohol engine are also not likely to be as obnoxious as the odor of gasoline and its products of combustion.

◆

Wireless Telegraphy in Airships.

The German airship "Gross II." is provided with wireless telegraphic apparatus. According to newspaper accounts, good results have also been obtained with wireless apparatus on the "Zeppelin III." This announcement is especially gratifying, because doubts had been expressed concerning the advisability of attempting wireless communication with Zeppelin airships, on account of the danger of fire. The Zeppelin airship, unlike those of Parseval and Gross, has a metallic skeleton which is a good electrical conductor, and it is also exposed to the danger of an accumulation of an explosive mixture of gases in the space between the gas bags and the outer skin.

The Current Supplement.

An interesting aerial cableway and ore-handling plant in New Caledonia is described in the opening article of the current SUPPLEMENT, No. 1769. The desirability of fitting the farm dwelling with good plumbing fixtures and of installing a modern lighting system and economical heating appliances, is pointed out in an excellent article on the subject entitled "Equipping the Farm House." Some simple practical inventions are enumerated—among them an automatic vulcanizer for automobile tires, a wrench with interchangeable dies, a wrench with tube for operating in corners, a [illegible] and [illegible]. A short but interesting article is that which describes a box with a secret drawer and [illegible]. The Paris correspondent of the [illegible] contributes a description of [illegible] system of [illegible]. Methods for making [illegible] are described and illustrated. The development of the [illegible] is [illegible] traced. Those interested in the return of Halley's comet will find in the current [illegible] a good ephemeris which gives the [illegible] the comet up to December [illegible]. [illegible]

[illegible]

[illegible] BY ARRANGING NUMBERS.

To the Editor of the SCIENTIFIC AMERICAN

[illegible] for some time your correspondence column [illegible] a lot of matter on magic squares. Recently [illegible] came to my notice which is somewhat different from magic squares but which must surely be [illegible] by a system. The problem is to arrange the numbers from 1 to 15 in seven different combinations of five rows and three numbers in each row so that no two numbers will be in the same row more than once. Of course, it is quite apparent that any number can be combined with seven different pairs but by what system can this or any similar problem be solved?

CONTROLLING STEAMSHIP ENGINES FROM THE BRIDGE

To the Editor of the SCIENTIFIC AMERICAN

I noticed in a recent issue the suggestion by some reader of letting the engineers on ocean-going vessels and in fact all large steamers, see where they are going, and judge the speed for themselves, as when making a landing.

In this connection I would say that besides the trouble mentioned by you there would be the even more serious one of having two men each thinking separately, and each figuring on what to do without knowing what the other will do For example in case of an apparently impending collision the pilot sees that by making a quick turn he can avoid it. The engineer sees the situation and not figuring on the possibility of steering away backs his engine The result would be the vessel would not answer her helm quick enough with disastrous results

Now there is a system of control on a large number of motor boats, in fact on motor boats up to and including 75-footers called one-man control which is nothing more or less than bringing the engine controls to the steering wheel as on an automobile

Steering a very delicate operation is done by steam Why with a similar apparatus cannot a large vessel be made a "one-man control" boat? There is no great mechanical difficulty to it And what is more a steam engine could be entirely controlled by one lever whereas a gasoline motor takes three—reverse gear spark, and throttle

I would like to hear what others have to say on this subject.

Some Curious Number Puzzles.

BY J F SPRINGER.

There are many curious things about numbers Some of these afford the basis for puzzling games To the uninitiated the results have a more or less wonderful appearance In the following article it is proposed to instance and explain certain of these puzzles The first is somewhat similar to a puzzle published by Mr W W R Ball The others are new and appear now for the first time

To begin with—there is the puzzle of the reversed digits A person is requested to select a number having in it an odd number of digits. He is next asked to reverse the order of the figures thus producing a second number Now he is directed to subtract the one number from the other and multiply the result by any number he pleases cutting off any naughts at the end Upon obtaining this he is to cross out the final two figures and tell you the resulting number He will probably be surprised to have you tell him the figures which he crossed out. You do this by annexing two naughts at the end of the number he tells divide by 99 and note the remainder This remainder subtracted from 99 yields the number crossed out by him.

Thus suppose the number chosen to be 58463 (an odd number of digits) Reversing this, we have 36485 Subtracting one from the other we obtain 21978 Multiplying this by 23 (any number will do) we get 505494. Crossing out the final two digits (94) we are supposed to be told the result—5054. To this we annex two naughts—505400. Dividing by 99 we get for remainder 5 Subtracting this from 99, we get the crossed-out number 94.

To understand the underlying reasons is not difficult. Thus, suppose the original number possessed, say, three figures. It can be represented algebraically by the expression $100x + 10y + z$, when x, y and z represent the several digits. The reversal of this is [illegible] from the other, we [illegible] evidently divisible [illegible] will still be true if we [illegible] The number then [illegible] and after [illegible] by 99. Cut[illegible] divisibility by 99 [illegible] not able [illegible] the two crossed-out figures by naughts, we have a number which lacks something of being divisible by 99 or does not. In either case what needs to be added to bring the remainder up to 99 is the number crossed out If the remainder is naught then the number crossed out was 99 itself

Another puzzle where two figures are determined by the performer is the following A person is asked to select two prime numbers He is then to add them and square the result For a moment this is to be set aside Next the smaller of the primes is to be taken from the other and the resulting difference squared This last result is then to be subtracted from the result laid aside a moment ago You now request to be told the result. This you divide by 4 You will then obtain a number which can be factored in but one way yielding two prime numbers. These are the numbers selected at the outset

To illustrate suppose the prime numbers selected are 7 and 13. Adding and squaring you get 400 Subtracting and squaring there results 36 Subtracting this last number from 400 you have 364 Dividing this by 4 you obtain 91 This can be factored in but one way—7 × 13

To explain the matter algebraically let x and y represent the two prime numbers Adding and squaring we get $(x + y)^2$ Subtracting and squaring we have $(x - y)^2$ If now we write these expressions out in full and subtract the second from the first thus

$$(x^2 + 2xy + y^2) - (x^2 - 2xy + y^2)$$

we shall get $4xy$ This is the number told to the performer corresponding to 396 above Dividing by 4 we of course get just xy As both x and y are primes their product is factorable in just one way—into x and y

A third puzzle is when a person is requested to select a number He is then to square it and lay aside for a moment You then request that he take a number which is one less than the one selected and square this also He is now to subtract one square number from the other and tell you the result You then add one to the number he tells you and divide by 2 This will give you the original number

Again suppose that instead of subtracting one and then squaring your friend had been asked to subtract 2 and square You will then request the two squares to be subtracted the one from the other and the result communicated to you just as before You now add 4 and divide by 4 getting for result the number chosen

Thus in the first case if the number chosen were 13 the square would be 169 The square of one less than the number $(13 - 1 = 12)$ would be 144 Subtracting 25 is obtained This is the number communicated to the performer Adding 1 and dividing by 2 we get 13—the original number

In the second case after squaring 13 and getting 169 we square $13 - 2 = 11$ and get 121 Subtracting this from 169 we obtain 48 Adding 4 and dividing by 4 as directed we obtain 13

Algebraically considered we have for the first case $x^2 - (x - 1)^2$ as the number told to the performer This is really $2x - 1$ If we call this number N we have $N = 2x - 1$ Now N is known and we wish to get x

We have therefore $x = \dfrac{N+1}{2}$

In the second case we have $x^2 - (x - 2)^2$ which yields $4x - 4$ Putting $N = 4x - 4$ we get

$$x = \frac{N+4}{4}$$

Or to state the puzzle in a more general form we may request that the number to be subtracted be A instead of 1 or 2 as before We have then $x^2 - (x - A)^2$ This gives $2Ax - A^2$ Putting $N = 2Ax - A^2$ and solving for x we get $x = \dfrac{N + A^2}{2A}$ By using a formula such as this we may keep up the mystification by continually changing the number to be subtracted We have simply to remember that we add to the number told us the square of the number subtracted from the original number and then divide by twice this number (but without squaring) Thus if we tell the person to subtract 7 and then to square the result, at the end when he tells us the result of all his operations we have simply to add 49 $(= 7^2)$ and divide by $2 \times 7 = 14$

Again, you request some one to square two consecutive numbers and add the results You then ask that he double this amount and subtract one You are then to be told the result. If he has performed his operations correctly this will be a perfect square You take the square root This will be the sum of the original consecutive numbers. By subtracting 1 and dividing by 2 you will determine the smaller The other one is of course obtained by adding 1

Thus, suppose your friend selects the consecutive numbers 11 and 12. Squaring and adding he gets 121 + 144 = 265. Doubling this and subtracting 1 he obtains 529. This is a perfect square it is the number he tells you. Taking the square-root you find it to be 23 Subtracting 1, and dividing by 2 you get 11 The original numbers are therefore 11 and 12.

To explain the matter algebraically we write $x^2 + (x + 1)^2$ as the sum of the squares of the consecutive numbers The next operation is expressed thus $2[x^2 + (x + 1)^2] - 1$. This gives $4x^2 + 4x + 1$ This is the number told the performer and should be a perfect square It is In fact it is equal to $(2x + 1)^2$ Subtracting 1 from the square root the result is $2x$ Dividing by 2 the smaller of the two consecutive numbers is obtained

Still another puzzle consists in the following procedure You ask the "patient to select a number of any number of digits He is then to form with the same digits a second number by rearranging the digits in any way agreeable to himself These two numbers are then to be subtracted the one from the other and the result multiplied by 33 You now request that any naughts that may be at the right hand end be cut off He is then to cross out the final pair of digits and tell you the number remaining after this is done You annex two naughts divide by 99 and subtract the remainder from 99 The result will be the figures crossed out

This puzzle depends for its success upon the fact that when two numbers formed of precisely the same digits but differently arranged yield upon the one being subtracted from the other a new number divisible by 9 Upon multiplying this by 33 it will still be so divisible and will in addition contain 11 as a factor In consequence of containing 9 and 11 as factors it will contain 99 $(= 9 \times 11)$ as a factor The explanation of the remaining procedure is the same as that given in the case of a preceding puzzle That two numbers having the same digits but differently arranged will yield a number divisible by 9 may be seen by considering the following equations

$$10000w + 1000x + 10y + z - (10000y + 1000x + 100z + w) = 9999w - 9990y - 99z = 9(1111w - 1110y - 11z)$$

To illustrate this puzzle suppose the number selected is 46309 Rearranging the digits we get say 60349 Subtracting 46309 from 60349 we get 14040 We now multiply by 33 and get 463320 Observing that this has a naught at the right hand end we cut it off obtaining 46332 We now cross out the 32 and get 463 as the number which would be told to the performer He annexes two naughts and gets 46300 This he divides by 99 obtaining 67 for the remainder He subtracts this from 99 and gets 32 the number crossed out

A New Fare Box for Pay-as-You-Enter Cars

A new fare box for pay as you-enter cars has made its appearance in New York It differs in almost every way from the usual contrivances of its kind In the first place it not only collects and registers nickels but gives the conductor access to the cash after it has been registered and thus renders it unnecessary for him to fill his pockets with change before he starts out on his trip In the second place the new fare box enables the conductor to detect mutilated and counterfeit money for the coin slides down a glass covered chute and is therefore visible If the conductor discovers that it is a counterfeit the coin is mechanically dropped into a special receptacle and returned to the passenger If the coin is good it is registered and caused to drop into a cash drawer Although it is not likely that a dishonest conductor would attempt to abstract so small a sum as a nickel by turning the box upside down so that the nickel would run out an automatic gravity closure has been provided which effectually blocks the chute if the attempt should be made so that the fare must pass through the apparatus in the regular way The width of the chute is just large enough to accommodate a good nickel A larger coin cannot enter and a smaller coin is mechanically returned by the machine Each conductor is held responsible for the fares registered Although he has access to the cash collected the amount turned in must be the amount recorded Thus a very simple and effective check is provided without the necessity of giving the conductor a large amount of small change with which to start his trip The boxes are made of a special composition of metals and weigh only 10 pounds

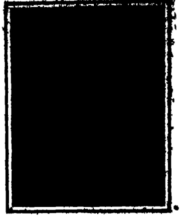
Peat fuel will be used in an electric station being erected in Germany The new plant is being installed in the region to the southwest of Oldenburg and it lies in the vicinity of extensive peat fields from which the supply is to be secured The electric plant is laid out on a large scale and when completed it will be one of the largest in the country It is to furnish current over a network of power lines which will cover the entire Duchy of Oldenburg with a radius of 40 miles Probably the new station will be completed about the end of next year and in the meantime measures are being taken to find out about what amount of power will be taken in the various cities and towns within the area.

SOUNDING THE OCEAN OF AIR ABOVE US.

ATMOSPHERIC EXPLORATION



The science of meteorology has so far progressed that we know with considerable accuracy the nature composition and general properties of the lower air If meteorology is to become anything like an exact science in other words if we are to predict the weather not only of tomorrow but even of next week with more accuracy than is now possible we must have at our disposal data which will enable us to determine the condition of the upper layers as well and their effect upon the lower layers In the interest of that investigation we find that the modern meteorologist has been conducting for the last two decades investigations that will sooner or later bring together an enormous mass of facts which the mind of some master meteorologist will some day whip into a scientific correlation

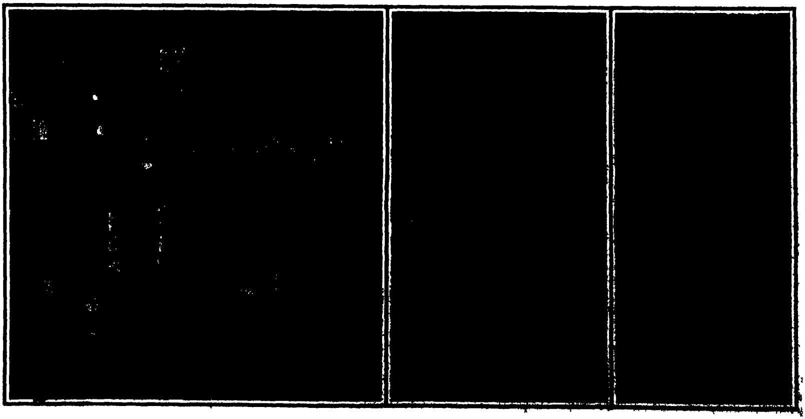
In this effort to discover the physical attributes of the upper layers of the air barometers hygrometers thermometers and wind gages are employed The barometer measures the weight of the air the hygrometer its moisture the thermometer its heat the wind gage its velocity These instruments all of them well known in meteorological research have been considerably modified for the study of the upper air a modification necessary because they must be lifted to great heights by means which make it impossible to employ great weights Hence it is that they are made of feathery lightness and are ingeniously combined The combination is usually known as a meteorograph Thus the thermometer and barometer are merged into a meteorograph specifically known as a baromethermograph a contrivance which is provided with two automatic styles one of which writes down the pressure of the air and the other its varying temperature Sometimes the barometer thermometer and hygrometer are joined in a single instrument which notes the humidity as well as the pressure and temperature The records are made upon clock driven cylinders covered with lamp black because no ink has been found which will not freeze in the bitter cold of the upper air At lower levels special inks and paper can be employed The construction of these meteorographs has involved not a little ingenuity Perhaps the men who have contributed most in devising special forms of instruments are Mr S P Fergusson and Mr H H Clayton of the Blue Hill Meteorological Observatory in this country

Fifty years ago the experiment was made of intrusting instruments of precision to venturesome balloonists Because a human being cannot live in the thin air of great altitudes these experiments sometimes proved fatal Hence it is that the meteorologist has adopted in a measure the methods of the marine biologist In other words he sounds the ocean of air at the bottom of which we live

His sounding methods are dependent upon the employment of kites and free unmanned balloons By their means it has become possible to elevate the delicate instruments which automatically record the physical condition of the upper air and to bring to the earth an accurate account of atmospheric happenings many miles above the earth s surface The men to whom most of the credit for this new means of investigation is due are Prof A Lawrence Rotch of the Blue Hill Meteorological Observatory in this country Dr Richard Assmann of Germany and Teisseren de Bort of France

The exploration of the upper air by kites has been carried to the greatest perfection by Prof Rotch It may safely be said that his study of the lower four miles of air is the most complete that has yet been made The kites employed by him and for that matter by almost every meteorologist—are of the open box type invented by Mr Lawrence Hargrave The kites often measure 9 feet in length Such is the pull exerted by them that it is impossible to employ muscular power to control them For that reason they are hauled in by engine driven winches Devices are employed which register the pull of the kite and the length of the line in use Often it happens that as much as ten miles of line may be paid out In spite of the great lifting capacity of such a kite it could not attain any considerable height if it were held by hemp alone A cord or rope would necessarily be so heavy and thick that a kite would be severely taxed in pulling it up Hence it is common to employ fine music wire which is both strong and light. The elevation attained by a kite is determined in fair weather by means of théodolites. At night and in hazy weather the meteorograph readings themselves must be depended upon

Four miles may be considered the maximum height that a kite is capable of attaining To sound the reaches of air above that level, the free or unmanned balloon is employed of which the most skillful use has been made by Teisserenc de Bort and by Dr Richard Assmann These free balloons are filled with pure hydrogen gas which expands with increasing elevation Since the degree of inflation obviously depends upon the height to be attained considerable care must be taken not to fill the gas bag entirely If the balloon is to reach a point where the air is one-half as dense as at the level of the sea the gas bag is filled about one-half If a height is to be attained at which the air density is one-fourth that at the level of the sea the bag is filled about one-fourth. It is very evident that for the attainment of very great heights the balloon s capacity must be great and the construction exceedingly light This explains why instruments of feathery lightness must be employed Originally fairly large paper balloons were employed for the purpose by Teisserenc de Bort but the India-rubber balloons of Assmann have now taken their place These India rubber balloons vary in diameter from three to five feet They have reached considerable heights At the maximum elevation of the balloon the expansion of the hydrogen gas eventually bursts the bag In order that the instruments may not be dropped precipitously to the ground they are checked in their descent by a parachute Instead of a parachute a slightly inflated auxiliary balloon may be employed which does not explode and which has sufficient buoyancy to prevent a too rapid fall of the instrument Recently S Saul of Aachen Germany has advocated the use of two balloons connected by an aluminium pipe provided with a valve The weight of this pipe is much less than the netting generally applied to the balloon to carry the basket containing the recording instruments and is certainly much lighter than a para



Inflating a Saul double balloon. One balloon inflated. Both inflated.

The Saul double registering balloon.

SOUNDING THE OCEAN OF AIR.

[illegible] This arrangement is such that when the double balloon reaches its maximum height, the one bursts, and the other, not having sufficient buoyancy to carry the whole weight of the apparatus sinks slowly to the earth. At the same time it serves to attract the attention of the finder because it floats a few feet above the ground. The balloons can be filled in the open air, even in windy weather by one man whereas special care must be taken with the ordinary system.

To every basket in which the instruments of a sounding balloon are contained, a printed notice is attached which offers a reward for their return. A very large number of the instruments which drop to the earth thus find their way back to the observatories.

Sounding balloons reach astonishing elevations and travel at speeds varying from 40 to 80 miles an hour.

Although a large number of *ballons-sondes* were dispatched from St. Louis in 1904-7 under the direction of Prof. Rotch, none had been employed in the eastern States until last year. In May and July 1908 four *ballons sondes* were launched from Pittsfield Mass. with special precautions to limit the time they remained in the air and so prevent them from drifting out to sea with the upper westerly wind. Three of the registering instruments have been returned to the Blue Hill Observatory with good records. The first instrument sent up on May 7th was not found for ten months and the record is very interesting because it gives complete temperature data from the ground up to 17 700 meters or 11 miles. This is 6[illegible]0 meters higher than the highest ascension from St. Louis which by a coincidence was also the first one to be made there. On May 7th a general storm prevailed, so that the balloon traveling from the east was soon lost in the cloud and its subsequent drift could not be followed but the resultant course was 59 miles from the southwest as determined by the place where the instrument fell two hours later. A paper balloon will reach its greatest height in about six hours, a rubber balloon in three hours.

The air-exploring stations of the entire world have banded themselves into an association for the purpose of carrying on a systematic exploration of the upper air on agreed dates. Thus we find that each year an international week of exploration takes place in addition to the regular work of each observatory. These international weeks may fall in the spring, sum

GERMAN METEOROLOGICAL INVESTIGATIONS IN EAST AFRICA.

A SELF-ACTING MAIL ELEVATOR.

BY THE BERLIN CORRESPONDENT OF THE SCIENTIFIC AMERICAN.

The present methods of mail delivery in hotels, apartments, and office buildings are defective in many respects The letters and parcels are delivered to each lodger of an apartment house by hand, which obviously means waste of time and energy The system prevalent in some countries of handing all the mail matter to the doorkeeper or porter, to whom is left the care of distributing it to the various addresses, is also objectionable Nor can the letter boxes installed at the house door be called practical in all respects.

The idea of using the elevator principle for doing away with these drawbacks seems so simple, as to make one wonder that it should not have been long ago carried into practice As it is, a Berlin engineer, Mr E F Ostrowsky, has been the first to utilize it for the delivery of mail matter His system is of remarkable ingenuity and simplicity

One of our views shows a perspective of the mail elevator as designed for three stories of two tenants each Another view is a lateral section of the elevator A letter box installed on each staircase landing, and a façade, with a built in elevator, are also illustrated

The construction of the apparatus is based on a very simple mechanical principle.

In a narrow vertical shaft moves a frame *A* suspended by a wire rope, one end of which is fastened to the top of the frame *A*, whereas the other end passes over rollers *L*, and sideways, downward around the drums *G* and over another roller and opening in a board above the drum The end of the rope is fastened to a coiled spring which is connected with the lower part *B* of the frame *A* and imparting resiliency to the rope.

Because of this arrangement, the frame *A* can obviously be moved upward and downward, by means of the crank *H* and the drum *G*

In the frame *A* a letter box *M* divided into two equal parts is swiveled. The box has two apertures in both the front and back.

The rear wall of the elevator shaft is provided with openings communicating with the backs of letter boxes at the several stories. The openings are provided each with a hinged cover *C* opened by means of the levers *F*, *F*, *F*, connected with vertical rods.

The entire elevator shaft can be built directly into the vestibule floor in the case of new buildings as shown. Its external appearance can be made to resemble a column, in the case of existing houses. After dropping the mail matter into the proper compartment of the letter box *M* provided with special labels for each of the lodgers, according as the addressee lives in the left hand or right-hand wing of the house, the postman will lift the lever *F* corresponding to the story in question, thus opening through the medium of the lever *D* the gate *C* When the letter box *M* is lifted by turning the crank *H* at the high speed resulting from the considerable diameter of the pulley, it strikes against the open gate *C*, and, being tilted, pours out its contents automatically into the letter box, arranged on the staircase landing

As the gate *C* is opened, it strikes against the bell *K*, thus announcing the arrival of the mail An indicator on the receiving box is employed for the same purpose, the indicator remaining in a visible position until the letter box *M* has been emptied As the crank is turned backward the letter box is brought down to its original position

At the Fifth International Geographical Congress, held at Bern in 1891, Prof Albrecht Penck, the well known geographer, proposed that the enlightened nations who were engaged in making maps of their own territory and of other countries should unite upon a common plan for the preparation of a general map of the world. He suggested that the scale of the map should be 1 1,000,000, or about 16 miles to the inch and that the separate sheets of the map should be so bounded by meridians and parallels that any two sheets representing adjacent areas should match except for distortion of projection, no matter by what country either sheet might be made This proposal led to resolutions and discussions at subsequent geographic congresses and to the preparation of several tentative maps by Germany, France, England, and the United States, in conformity with the general plan proposed by Prof. Penck.

The Russian Minister of War has undertaken to establish, by a succession of wireless telegraph stations, telegraphic communication between St. Petersburg and the far East.

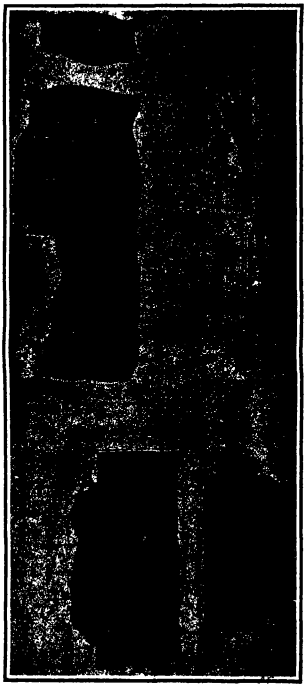
Treatment of Diseases of the Eye by Means of Intermittent X-Rays.

BY DR. A. [illegible]

It is to Cook of New York that we owe a new method of utilizing the Roentgen rays. The field for the usage of these rays seems to be unlimited; apparently, they will eventually prove to be of great therapeutic value for the various diseases of the eye. Possibly, even, if these rays are judiciously applied at the inception of infections which are supposed to be incurable we may thereby avert total loss of eyesight.

Let us first consider the production of intermittent X-rays, or, as they have been called by Dr David H. Coover, of Denver, U S. A., "the sparks of Roentgen rays." The apparatus specially in mind consists of a small motor, a condenser, and a movable scale.

My arrangement differs a little from that of Coover. It consists of a clockwork movement actuating a graduated rod provided with a movable screen. The rod is placed behind the localiser, and according to the position of the screen upon the rod, the interruptions follow one another more or less rapidly at the rate of from 50 to 200 per minute.



A MAIL DELIVERY SYSTEM FOR APARTMENT HOUSES AND OFFICE BUILDINGS.

With the aid of a regulator, one is able to obtain from 40 to 600 sparks per minute. The amperage and the distance of the tube are likewise carefully regulated. Experience has demonstrated that the best results are obtained in ocular affections by a somewhat restricted number of sparks, 75 to 150 per minute, and by removing the eye to a distance of about 37 centimeters from the focus.

It develops that radiant energy possesses four distinct therapeutic properties, namely, sedative, stimulating, irritating, and sloughing functions, each of which corresponds to an electrical, mechanical, chemical, and calorific effect.

With the intermittent rays it has been possible to separate the purely stimulating action from the irritative action, and experience has demonstrated that by thus proceeding, the regenerative action is enhanced.

Cook has [illegible] of the regenerative and [illegible] mitted, may [illegible] its [illegible] in the treatment of affections of the eye." If a cataract which [illegible] mature is exposed to continuous rays and [illegible] stimulations, an improvement of the eyesight is [illegible] or later followed by a maturation of the cataract, as a consequence of hyper-stimulation or irritation. This fact permits the establishment of a technical rule for the maturation of incomplete cataract. With the "sparks," especially when higher amperage is used, the irritation and the maturation are avoided; and with an incipient cataract the stimulations and regenerating effect are not only invariably obtained with more or less improvement in eyesight, but may be maintained during the entire treatment.

Dr. Coover may not have experimented with incipient cataract, but he has at least observed the regenerative action in other affections of the eye. In a case of serpiginous ulcer of the cornea new cells were rapidly formed, and a cure was effected only by application of the intermittent rays.

In the opaque portions of the cornea, the process of absorption results in a hyperemia of the blood vessels of the eye, as has been found in all cases which have undergone treatment.

The vessels of the conjunctiva are more congested after each treatment. The hyperemia persists for several minutes, and if there was previously a peri-corneous injection, it is always enhanced. Examination, by means of the ophthalmoscope, of the ball of the eye, after having been exposed to the rays, always shows an increase in the size of the vessel of the retina, particularly after a case of optical atrophy

The regeneration is accompanied by diminution of the tension, improvement of the circulation, and increase of the leucocytes. These modifications are noticeable in the muscular, nervous, osseous, vascular, epithelial, and glandular tissues.

The action manifests itself in the eye on the optic nerve, the cornea, the crystalline lens, the charoid, the retina, and the iris. In addition to the local effect, there is found another of a more particularly tonic nature. The cellular metabolism increases, and all the vital processes are stimulated, a condition which is necessary for the treatment of all local degenerations.

This effect, evidently, is totally different from that produced by continuous rays, which have a regenerative effect only during the early stages of their application This effect is particularly noticeable in the blood. At the start there is an increase in the number of red and white corpuscles, particularly the latter, and later, degeneration sets in, as is indicated by a diminution in the number of these corpuscles.

Some observations have been published regarding the cure of blindness and deafness by prolonged treatment with continuous rays employed for the treatment of cancer having its seat near the eye or the ear

Prof. Birch Hirschfeld of Leipzig has reported the anatomical modifications of an eyeball exposed to prolonged radiations during the treatment of a carcinoma (cancer) of the temple by the X rays. The principal troubles were due to the endothelium and to the vacuolization of the structures of the iris and of the retina. The macular region was the one most affected, and the seat of a cellular degeneration. There were no symptoms of inflammation. Experiments upon an animal led to the same conclusions. By his experiments with rabbits, Selenkordsky has likewise demonstrated the danger of immoderate or untimely use of continuous X-rays. This degenerative action of X-rays was likewise observed by me some years ago, and treatment of various cases led me to the same results as those of Cook. Having treated with the X-rays a woman forty-five years of age for a leucoma of the cornea complicated by incipient cataract, I was surprised to obtain a very appreciable improvement in the condition of the cornea, and likewise in the condition of the crystalline lens; but, in the measure in which the clearing up of the cornea was effected, an equally rapid development of the cataract occurred, so that it was soon completely operable. Enlightened by this experience regarding the peculiar effects of continuous rays, I have used [illegible] restraint in treating cases by this method, and have never subjected my patients to a repeated treatment with X-rays. The technical details of the process of Cook and Dr. Coover seem to be rational [illegible] the observations of the latter lead me to [illegible] dently into the future regarding affections [illegible] even as optical atrophy.

It seems that in the acute [illegible]

(Continued on page [illegible].)

Handy Man's Workshop

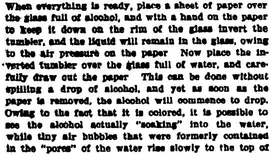
POROSITY OF LIQUIDS.

BY A. A. VAN DER VEER.

It is rather difficult to imagine liquids as having pores, though this seems to be the case as shown by certain familiar experiments. When a certain amount of powdered sugar is slowly poured into warm water, the water will dissolve the sugar and appear to absorb it without increasing its volume. Similarly, when alcohol is poured into water, the resulting volume will be less than the sum of the two volumes

ALCOHOL "SOAKING" INTO WATER.

For instance, if fifty parts of water and fifty parts of alcohol be mixed together, they will make only ninety-four parts. Apparently one of the liquids has entered into the "pores" of the other This experiment as commonly performed in physics laboratories consists in putting measured quantities of the two liquids together, but the effect would be far more striking were it possible for students to see one of the liquids actually 'soaking" into the other This can be done in the following way Take two glasses, one filled to the brim with water, and the other with alcohol. In order to show the effect to better advantage, color the alcohol with red ink. The glasses should not be over-full, that is, the surface of the liquid should not bulge above the rim of the glass. When everything is ready, place a sheet of paper over the glass full of alcohol, and with a hand on the paper to keep it down on the rim of the glass invert the tumbler, and the liquid will remain in the glass, owing to the air pressure on the paper Now place the inverted tumbler over the glass full of water, and carefully draw out the paper This can be done without spilling a drop of alcohol, and yet as soon as the paper is removed, the alcohol will commence to drop. Owing to the fact that it is colored, it is possible to see the alcohol actually "soaking" into the water, while tiny air bubbles that were formerly contained in the "pores" of the water rise slowly to the top of the tumbler This will continue for some little time until a considerable air space forms in the top of the tumbler.



INVERTING THE GLASS FULL OF ALCOHOL.

PLATING SPOONS AND FORKS AT HOME.

BY A. J. FARMAN.

In the home of every handy man there are generally some forks or spoons that have become somewhat the worse from wear. Every such article if in a moderately good condition is worth replating, and if the work is done at home as much silver can be deposited as one desires, so as to give a coating that will last for years. The following directions will enable any handy man to silverplate his own goods in a very satisfactory manner, with such silver as there happens to be about the house, such as an old silver watch case, a [illegible] [illegible] silver [illegible] or two, or an [illegible] [illegible] [illegible] [illegible] of silver [illegible] [illegible] [illegible] [illegible] commodity [illegible] [illegible] [illegible] ounces and a half of pure granulated silver at about sixty cents per ounce. Assuming that the old silver mentioned is to be had, proceed as follows. Procure a small stoneware pot of about one or two quarts capacity Weigh the silver—there should be about two ounces. If there are any iron or steel rivets or rings about the watch case, or any German silver parts, break them off with a pair of pliers. Place the silver in the crock, pour upon this four or five ounces of nitric acid (chemically pure) of a strength known as 38 deg. Place the crock into an enameled tray Pour some hot water into the tray, to aid the chemical action Place a sheet of glass upon the pot, or a stoneware lid if it is provided with one, then stand the pot out of doors, because the fumes that are given off are poisonous In the course of half an hour, all the silver will have become dissolved Now fill the pot half full of cold water, to dilute the nitrate of silver that has been formed. The liquid will present a bluish green appearance, due to the copper contained in the old silver articles. Take four ounces of hydrochloric acid, and add to it four ounces of water Then pour this into the silver solution. Stir vigorously while this is being added, with a clean glass strip. The silver will now be thrown down as chloride of silver, in the form of a dense white precipitate Let this stand for about two hours, to allow the chloride of silver to become precipitated, carefully pour off the clear bluish green liquid, without disturbing the precipitate. Fill the pot again with clean water, stir well, and let it subside again for a couple of hours Repeat this four times This operation will free the chloride of silver of the dissolved copper, also the result of chemical decomposition. *If pure granulated silver is used* proceed in the same way, only in this case there will be no copper impurities to be gotten rid of Procure a three-gallon crock, with plain upright sides, pour the chloride of silver into this, wash out every scrap of chloride Pour these washings into the crock, then dissolve half a pound of cyanide of potassium in the jar that the silver was dissolved in The cyanide must be that known as 99 per cent commercial three pints of water being used When completely dissolved, pour this upon the chloride of silver keeping in reserve about half a pint of the cyanide solution, stir the mixture with a glass strip wait a short time, and then, if the chloride has not become completely dissolved, add a little more cyanide solution When the chloride is completely dissolved add not more than four ounces of the cyanide solution, this will give what is known as free cyanide Add a quart of water, *stir and allow this liquid to stand twenty-four hours.* This will allow any dirt, also a small portion of carbon from the cyanide, to subside. Very carefully pour off the clear liquid, drain this off, return the clear liquid to the crock. After rinsing the crock out make the quantity of liquid up to two and a half gallons This is the silver-plating fluid

CONNECTIONS FOR AN OBLONG PLATING TANK.

A two-cell Fuller mercury bichromate battery will be just the thing for plating. Take a stout piece of copper wire, bend it in the form of a ring, so as to extend around the crock of the plating liquid, resting upon two strips of wood, obtain about one ounce and a half of pure silver and solder a piece of No. 16 insulated copper wire to it Attach this to the carbon of the battery, let it dip into the center of the plating crock, also procure some finer copper wire No 22 gage cut this into strips six inches long. Now take the forks and spoons, file down any badly worn parts, finish them off with some fine emery cloth glued to a flat strip of wood, and boil the lot in a saucepan with some strong washing soda and water to remove all grease. Scrub the fork or spoon with a fine-cut nail brush dipped into pumice powder, also wet the fingers and dip them into the pumice powder, so as to prevent any grease from coming into contact with the article. Scour the article well, twist one of the pieces of fine copper wire around the middle of the spoon, dip this into clean water, then quickly dip again into a solution of nitrate of mercury (one ounce of nitrate of mercury in one gallon of water) Rinse it again quickly in clean water, and place it at once into the plating liquid, suspending it from the ring of copper wire around the crock, which must be connected with the zinc of the battery About a dozen spoons or forks can be treated in this way the silver will take to the article at once. The sole use of the nitrate of mercury solution is to insure a perfectly clean surface, in fact chemically clean, which causes the silver to adhere firmly to the article As soon as six or seven articles have been placed into the plating bath they must be removed and brushed well all over with a brass-wire scratch brush, known as a hand scratch brush, which can be bought, with two rows of brass wire, for 35 cents. The article when so brushed must be returned to the plating bath to receive a further deposit, which may last for an hour or more according to the quantity of silver it is wished to put on To determine the quantity deposited first weigh the silver plate, called the anode when if at the end of one hour the loss has been 120 grains it will be known that 120 grains has been deposited upon the twelve forks or spoons. The articles must be removed every half hour and be scratch brushed This will rub down the white burn, as it is called, giving an even, smooth deposit.

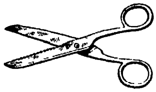
When all the articles have been plated and scratch brushed wipe them clean and burnish them by the use of a small steel burnisher or, if this cannot be obtained, use a very smooth and bright shoemaker's awl Hold the article with a clean cloth dip the awl or burnisher into a little soap and water stroke this carefully, with moderate pressure, up and down the spoon handle, and blend by continuing the stroking Then rub carefully over the back of the bowl while the curved part of the awl can be used to rub the inside of the bowl. Of course a little care is necessary not to cut or abrade the deposited silver Polish the article with a piece of chamois leather dipped into fine rouge, moistened slightly, and finish off with a clean chamois leather, It is important that the circuits through the several articles have the same resistance otherwise more silver would be deposited on one than on the other The diagram shows how this is accomplished when an oblong tank is used The circuits through *A B C* and *D* are all of the same length

---

SCISSORS WITH A SAW-TOOTH.

BY W J C

A very handy tool can be made from an old pair of scissors or shears as shown in the accompanying sketch One blade is cut with a set of saw teeth inclined toward the handle These teeth hold the material fast, and prevent it slipping toward the point of the shears. Rubber sheeting strips and all kinds of soft packing can be easily cut with square or inclined ends. It matters not in what position the scissors are held, they will cut without slipping In using these scissors for rubber and other slippery goods, the saw toothed blade should be on the bottom to obtain the best results Heavy rubber and packing can be cut with less effort, as it is not necessary to hold the scissors against the goods to prevent slipping The same design of lower blade can be applied to plumbers and metal workers shears with a change in the relative positions of the holding and cutting blades If the saw toothed blade is kept on the bottom of the goods the edge will be left rough but by reversing the shears so that the saw teeth come on top the edge is left just as clean as if no teeth were used The piece cut off however is rough on the edge The scissors can be used to cut paper cloth or any other material, if the saw teeth are kept on top or bottom, according as it is desired to have the smooth edge on the left or the right hand piece cut off

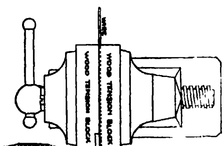


SCISSORS WITH A SAW-TOOTH BLADE.

HOW TO WIND AN OPEN SPRING

BY OTTO KARNER

An easy way to wind a spring of the compression type will be found in the accompanying illustration The mandrel on which the spring is wound is selected according to size of spring wanted In this case the mandrel and the end of the wire were fastened in the chuck of a carpenter's brace The piece *A* is a narrow strip of metal the thickness of which regulates the spacing of the coils If a closed tension spring is wanted the piece *A* is left out entirely The wooden tension blocks are clamped with the proper tension in a vise If no vise can be procured an ordinary clamp will answer the purpose

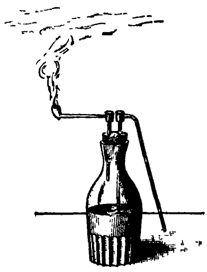


METHOD OF WINDING AN OPEN SPRING

THE SELF-SMOKING PIPE.

After filling a decanter about two-thirds full of water close it by means of a cork provided with two apertures Through one of these pass a short pipe stem and through the other a longer stem that enters the liquid

To the smaller tube affix a cork provided with two apertures The apertures may be easily formed by means of a red hot poker The lateral aperture serves to fix the pipe. Finally, with the other cork and a bent tube, form a siphon After the latter has been primed and is once in operation it will tend to empty the decanter, and the vacuum formed will be immediately filled by the external air flowing in through the pipe. It is then only necessary to light the latter in order to see it "smoke itself" tranquilly as long as any water remains in the decanter



THE SELF-SMOKING PIPE.

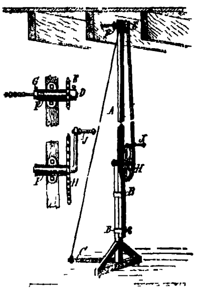
This experiment is a very interesting one and may easily be performed

HOME-MADE KNOB AND TUBE BORING MACHINE.

BY R. H BROCKMANN

To electricians who install knob and tube wiring a machine that will bore the overhead beams is a great time and labor saver The drawing shows a machine for this purpose that can be easily and cheaply made by anyone handy with tools.

The framework *A* is made of hard wood, oak or hickory, firmly put together and made long enough so that when fully extended it will reach ordinary high ceilings. The height can be adjusted by means of the sleeves *B* and the thumb-screw If it is too much bother to make the sleeves *B* ordinary iron clamps can be used *C* is a piece of wood fastened to the frame by means of a hinge at one end and a light flexible wire cable at the other *E* Points are formed at the bottom of the frame to keep the machine from slipping



HOME MADE KNOB AND TUBE BORING MACHINE.

A piece of machinery steel *D* is drilled to form a socket for the bit It is turned down to form a shoulder at the socket end and is then held in the ½-inch drop tee *F* while Babbitt metal is poured in to make the bearing A nine- or ten-tooth bicycle sprocket *E* is mounted on a bushing and fastened to the shaft with a set screw A set screw *G* is also provided to hold the bit in place Round shank bits are intended to be used The drop tee *F* is then fastened to the frame *A* by means of bolts. The sprocket *H* and crank and pedal *J* of a bicycle are mounted in a ¾-inch drop tee *I* and given a good bearing by pouring Babbitt metal around the axle. A hole is then bored through the other end of the axle and a washer and pin put on. The rat trap or cage part of the pedal is removed, this leaves the central part with the ball bearings, which makes a very good handle. The drop tee *I* is then bolted to the frame *A* and a bicycle chain *J* is fitted onto the sprockets *A* and *K*

To operate the machine, a bit of the proper size is inserted into the socket. The frame *A* is then extended to the proper height and made fast by means of the thumb screw The operator then places the machine in position with the bit against the beam, and with his foot bears down the pedal *C*, thus forcing the bit firmly against the beam, while he bores the hole by turning the handle *J*

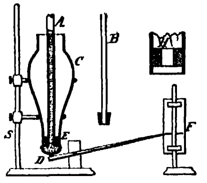
INEXPENSIVE APPARATUS FOR ILLUSTRATING THE "HYDROSTATIC PARADOX."

BY F R. GORTON.

A simple method for illustrating the "hydrostatic paradox" with inexpensive materials is described below

In the small end of a large lamp chimney *C* is cemented with plaster of Paris or paraffine the neck of a bottle of suitable size to fit a large rubber stopper (see *H* in figure) Across the small end of the chimney is tied a piece of thin sheet rubber *D* A small glass tube *B* and a larger one *A* are provided with rubber stoppers which fit well in the aperture *H* The apparatus is mounted firmly on the ring stand *S* as shown in the cut.

In the manipulation, tube *B* is inserted in the inverted chimney and filled with water to the level of the open end of *C* As the force exerted by the water against the rubber increases, the index rises The final position of the index is marked by a heavy black line on the cardboard which slides on the vertical rod *F* Now tube *B* is removed and the larger tube *A* inserted and filled to the same level The index rises promptly to the height marked by the line on the card *F* Finally tube *A* is removed and the chimney is filled to the brim. The index rises to the same point as before



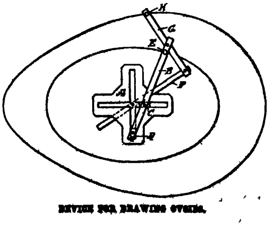
APPARATUS FOR ILLUSTRATING THE "HYDROSTATIC PARADOX"

One of the chief merits of the device is the fact that no water has to be removed from the apparatus during the experiment —School Science and Mathematics.

DEVICE FOR DRAWING OVOIDS.

BY J O. BROUILLET

The instrument illustrated herewith can readily be made by any handy man and will enable him to draw ellipses of various sizes and ovoids as well It consists of a sheet metal piece *A*, in which two slots are cut crossing each other at right angles A lever *B* is provided with two blocks *C* and *D*, adapted respectively to slide in the slots. A lever *F*, which is fulcrumed at the center of the plate *A*, is connected by means of a lever *G* with the end of the lever *B* A pencil may be fitted through a hole in the lever *B*, and as this is revolved around the plate *A*, it will trace an oval or elliptical line. At the same time a pencil in the lever *G* will trace an ovoid, as indicated in the drawing.



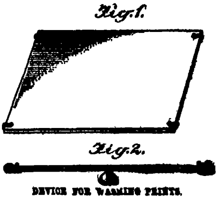
DEVICE FOR DRAWING OVOIDS.

DEVICE FOR WASHING PRINTS.

BY [illegible]

The device pictured herewith was devised to prevent prints from becoming torn while being washed. It is especially adapted to washing large prints, such as bromide enlargements, and is of such a simple construction that photographers will probably find it convenient to make several of them and thereby save much delay.

The material necessary is a quarter-inch board of slightly larger dimensions than the photograph to be washed, and four narrow steel springs; segments of a clock spring answer the case admirably. Each spring is clamped on the upper side of the frame, so that it turns over on the other side and securely holds each corner of the print. Besides the ease gained in moving the prints about, without injuring them, the photographs are always completely immersed if simply left to soak.



DEVICE FOR WASHING PRINTS.

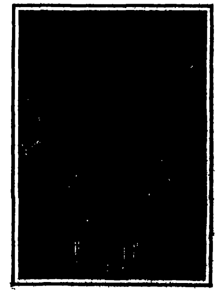
BLUE ROSES.

BY PROF GUSTAVE MICHAUD, COSTA RICA STATE COLLEGE.

The roses shown in the accompanying figure are white with a delicate and beautiful network of blue veins. Such roses can be obtained in little more than one hour by placing the following solution, instead of water, in the vase in which the cut ends of the stalks are dipping

Water	100 cubic centimeters.
Aniline methylene blue	2 grammes.
Potassium nitrate	2 grammes.

School boys know that white roses can be transformed into red flowers by allowing the cut end to remain some time in some kinds of red ink. The writer tried to obtain similar results with a number of aniline dyes and found that while some, like aniline red scarlet, for cotton readily rise into the vessels of the stalk, others, like aniline methyl green, will not under any circumstances reach the flowers. Some common salts were added to the dyes and one of them potassium nitrate (saltpeter) was found to exert a powerful influence over the ascent of the dyes, which rise then rapidly and in considerable quantities. The experiment is curious and should be repeated while using the blue liquid, the end of a few stalks being placed in some of the solution to which no saltpeter is added Aniline methylene blue is not one of the dyes which readily ascend in plants and it will be soon noticed that, while the flowers with the stalks dipping into the saltpeter and blue dye solution are covered with the blue network, nothing can still be detected on those whose stalks are allowed to dip in the same liquid but without saltpeter.



THE ROSES ARE COVERED WITH A NETWORK OF BLUE VEINS.

Will some botanist suggest an explanation of this influence of saltpeter on the ascent of dyes in stalks and flowers?

[illegible] PATENTED INVENTIONS.

Pertaining to Apparel.

[illegible]-STRETCHER.—R. N. HALLETT, [illegible]. This stretcher can be folded for packing for the convenience of travelers, the side bars having sections in which the stretcher members are pivoted, a central rod being provided, which has means for operating the stretcher members, which have means for limiting their movement away from the side bars.

Of Interest to Farmers.

PLOWING-MACHINE.—D. F. KUSTER and G. L. NIEMANN, Washtucna, Wash. This device may be used for disking and throwing the dirt either to the right or left, thus making it possible to go along the side hill, and when the end of the strip is reached the machine may be reversed and retraced along the same side, throwing the dirt down hill.

PLOW.—H. H. JULACH, Mount Hope, Wis. Among the principal objects of this invention is to provide a share which may be readily and quickly detached from the plow and as readily and quickly replaced, thereby permitting the operator to separate the part of the implement which requires sharpening, and to carry the same to the forge or blacksmith shop.

Of General Interest.

HOLDER FOR CONCRETE-REINFORCING.—J W REED, Hammond, Ind. The holder is constructed of a single piece of wire the same being bent to form an eye to embrace the reinforcing bar, with the end portions of the wire extended from the eye to provide nail prongs, the prongs being offset intermediate their length to provide striking faces, said nail prongs arranged to open the eye when spread apart, whereby the eye may be sprung over the bar

COMBINED HAMMER AND SIGHT.—A M. POWELL, Valdez, Alaska. This inventor employs a front sight and a hammer provided with an extended portion having a hole through it and also having a notch disposed adjacent to said hole, the notch and hole being in vertical alinement relatively to each other and to the front sight when the barrel and hammer occupy their normal positions, so that either the hole or notch of the hammer sight may be alined with the front sight.

QUOIN.—M. MUCHLER, New York, N Y In view in this invention are means that prevent the separation of the wedges either by a relative endwise or lateral movement, and also means including a ratchet bar to automatically lock the wedges against endwise movement in a direction to decrease the thickness of the quoin, the rack bar being movable into and out of operation

HOLDER AND PROTECTOR FOR MUSICAL-INSTRUMENT STRINGS.—O. J MÜLLER, New York, N Y The aim in this case is to provide a holder for the strings, which will operate not only to retain the string in coiled form but will protect it against injury The string may be readily inspected without removing it from the holder, and is so secured in place that it may be very readily removed when desired

DISPLAY BOX AND TRAY.—E M. LEWIS, Moundsville, W Va. This combination box and tray is for use in packing goods, intended to be displayed by the retailer, in the original boxes as received from the manufacturer The invention is inexpensive enough to be applied to the cheapest box and at the same time so complete that it may be used with the most elaborate and costly creation of the box makers' skill

STARTING AND SEPARATING GATE.—R V JONES, Seattle Wash It is the object in this instance to obviate race starting accidents by providing means for locking each horse in a separate inclosure and starting the horses a sufficient distance apart, in order that they may not trample upon each other, nor allow the jockeys to interfere with one another when the horses start.

METHOD FOR FORMING SHEET METAL BODIES.—L N JONES, Defiance, Ohio. The intention of the inventor is to provide a method for forming the bodies in a very simple and economical manner and without danger of rupturing the sheet metal, and permitting the formation of the regular shaped bodies without the use of expensive machinery

LABIAL PROTECTING MEANS FOR DRINKING GLASSES, BOWLS, CUPS, SPOONS, AND THE LIKE.—L. JANCSY, 35 Rue des Martyrs, Paris, France. The invention relates to means adapted to prevent the lips from coming in contact with the edge of drinking receptacles. This labial means is substantially constituted by a part of varying shape sliding upon the edge of the glass and holding itself on the same, either in virtue of the nature of the substance comprising it or in virtue of its shape or its arrangement

SAFETY-ENVELOP.—R. HASEL, New York, N. Y. The envelop is of such a character that the various portions possess gummed surfaces, the arrangement of the various gummed surfaces being such that when the envelop is once sealed, the contents cannot be reached except by mutilating several layers of paper, disposed one upon the other and thoroughly bonded together.

[illegible]-CHUTE.—A. A. HARRIS and B. G. [illegible], [illegible], Mich. The invention relates particularly to the provision of hinged side doors for relieving pressure within the chute and allowing the lateral discharge of the beans as the bin is filled, the doors and spring attachment thereof being so applied as to offer no material obstruction to the withdrawal of the chute from the bin, when it has been filled.

DENTAL TOOTH CLAMP.—G A. HARPER, Shreveport, La. In this dental appliance the improvement is in the nature of a clamp for application to a tooth and having means for holding cotton rolls or napkins, such as used by dentists in keeping moisture away from a tooth while filling the latter, and also means for supporting a mirror

Hardware.

SCALE.—S. C COOPER, Nunda, N Y In this patent the invention refers to measuring instruments, and the intention is to provide a new and improved weighing scale arranged to permit the minute adjustment of the poise to insure accurate weighing and to allow convenient reading of the result.

SEAL ATTACHMENT FOR LOCKS.—C H JOHNSON, Petaluma, Cal The invention is intended for use especially on locks used on suit cases, trunks, boxes for legal papers, jewel boxes, and the like By the use of this device a seal may be placed over the lock and the same covered up and protected, so that the lock itself cannot be unlocked without breaking the seal.

Heating and Lighting.

STEAM-GENERATOR.—F N TILTON, Hartford, Conn. The object in this case is to provide a new and improved generator having no sharp bends and but few and straight joints between the pipe coils, the latter being arranged to permit ready assembling and to allow convenient access to any one of the coils.

Household Utilities.

SASH HOLDER AND LOCK.—T KEPHART Sinnamahoning Pa. For the purposes of this invention use is made of upper and lower runners fixed on a window frame and spring lever devices held on the sashes and adapted to engage the runners to hold the sashes open by frictional contact, the said lever devices and runners having interlocking means for locking the sashes in a closed position.

Machines and Mechanical Devices.

HOISTING APPARATUS.—H W BACHELDER, Schenectady N Y Means are in view in this improvement for swinging the boom, comprising two drums driven one from another to rotate in opposite directions, actuating means for the drums, and means for simultaneously connecting the actuating means with one of said drums and disconnecting the actuating means from the other drum

DRUM BATCH MIXER.—W R TUTTLE, Nunda, N Y The object of this invention is to provide a mixer which may be charged and discharged more quickly and thoroughly than those now in use one which will thoroughly mix and knead concrete and other materials, and one which has its members so constructed and disposed that the greatest strength and efficiency will be obtained.

AUTOMATIC PRESSURE CONTROL.—J H SMITH Rochester, N Y In this invention use is made of a cut-off valve located at the hydrant and having its outlet connected with the hose, so that on closing the nozzle gradually or abruptly a corresponding automatic closing of the cut-off valve takes place and on opening the nozzle a corresponding opening of the valve is had

SHAFT COUPLING.—F B RICHARDSON, Slidell, La This device while joining two shafts together with the utmost security, may be easily stripped from one of the shafts and permit of the latter's withdrawal through a bearing or other constricted place This is accomplished by constructing the coupling with a split collar and binding the two halves or portions thereof firmly together, when the coupling is assembled by an intermediate ring.

CLAY-GATHERING MACHINE.—C. E. OLDEN, Mason City Iowa. By use of this device dry clay may be collected without the necessity of digging the same and throwing the clay into wagons by hand. The clay may be scooped up into a proper receptacle and the latter can be emptied by means of levers and an appropriate clutch mechanism, thereby facilitating the unloading process.

PHONOGRAPH.—F M HOLMAN Silverton, Ore A record surface is provided in this case of a flexible nature, and having a relatively great length may be inserted or removed and in which the bearing members for the cylinder are pivoted to admit the removal or replacement of the record The record is applicable to the cylinder type in which the virtual diameter of the record is greatly increased, while the actual is not

Prime Movers and Their Accessories.

ROTARY ENGINE.—G SCHULZ, New York, N. Y. The more particular purpose of the inventor is to provide a type of rotary engine in which an explosive charge is first compressed by the immediate and direct action of the engine, and it is then exploded so that advantage is taken of its expansibility

Railways and Their Accessories.

RAILROAD-TRACK-RAIL HOLDER AND BRACE.—J. T WEST, Bowling Green, Ky The holder provides means for securing a rail upon a cross tie, by the lateral insertion of a spike through a depending member of each rail holder into the side of a cross tie whereon the rail is seated It is adapted for bracing the head of a track rail against laterally-applied strains.

CAR-COUPLING.—W S. LENNON, Tucson, Ariz. The invention relates to automatically operated car couplers. This automatic coupler may be operated without requiring the brakeman to pass between the cars. The coupler is ice and sleet proof, and it may be easily coupled without excessive jamming when the cars are on a curve.

Pertaining to Vehicles.

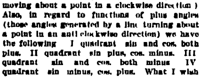
VEHICLE-WHEEL.—T HÜBSCHER, Weehawken Heights, N J This wheel is designed to offer little resistance to the air The rim with the tire may be readily detached and replaced and the wheel presents few parts on which dust and dirt may collect, and the tire bolts, air valve, and other parts of the inside of the wheel are protected from the weather

COMBINED STEERING AND DRIVING AXLE.—J W BUCHAN, Eastman Ga. In this patent the aim is to furnish a device which combines the features of a steering and driving axle and which is further provided with means whereby the wheel can be adjusted on the supporting sleeves of the steering knuckles as the bearings become warm

DUMPING WAGON.—T WRIGHT, Jersey City N J The invention pertains to dumping wagons and carts such as used by coal dealers in delivering coal The object is to produce a wagon having improved mechanism for raising the body into an elevated and inclined position for dumping the load The means are capable of raising the body to an unusually high elevation.

NOTE.—Copies of any of these patents will be furnished by Munn & Co for ten cents each Please state the name of the patentee title of the invention and date of this paper

---



Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th or will be sent by mail on request.

(12140) J C R writes We have in trigonometry minus as well as plus angles (A minus angle being one generated by a line moving about a point in a clockwise direction) Also, in regard to functions of plus angles (those angles generated by a line turning about a point in an anticlockwise direction) we have the following I quadrant sin and cos. both plus. II quadrant sin plus, cos. minus. III quadrant sin and cos. both minus IV quadrant sin minus, cos. plus. What I wish to know is, what are the signs of the respective functions of minus angles in the four quadrants, and the reason why? A There are several uses for the signs plus and minus. First to show the nature of a quantity as positive or negative second, as signs of the operations of addition and subtraction, third, to denote the direction of motion, as in the case of the angles produced by the rotation of a radius, which you specify, fourth to indicate the direction in which a quantity is changing or moving as in denoting north latitude by plus and south latitude by minus or the degree of the thermometer above zero by plus and below zero by minus. The functions of an angle in trigonometry are similarly denoted A line drawn upward from a horizontal diameter or to the right of a vertical diameter is plus, while one drawn downward from a horizontal and to the left from a vertical diameter is minus. With this rule or usage in mind there is no difficulty in giving the signs of all the functions in all the quadrants.

(12141) C D says I inclose a clipping concerning the Star of Bethlehem. Similar items have been going the rounds of the papers. What foundation is there for their statements? I can find no such star nor can I find anything in the reference books concerning the Star of Bethlehem I had supposed that the so-called Star of Bethlehem was one of our own planets probably Venus, and must some time have seen a statement to that effect but I can find no authority for it now A. There is no star known to astronomers as the Star of Bethlehem' Nor is there any star known which returns every 500 years The statements you send us in the clipping are the fanciful emanations of some fantastic brain It is barely possible that on a hazy night the planet Mars, which has been recently very brilliant in the evening sky, may have been seen to change in brightness and color as the haze passes over it, partly obscuring it. Such performances as the clipping describes cannot possibly have been seen in any heavenly body. There is no scientific knowledge regarding the "Star of Bethlehem," as described in the Bible. The Bible says all that anyone can say about it.

(12142) J W says I am going to construct a wireless, and wish to know the necessary apparatus for a 100-mile wireless sending and receiving apparatus. Would be very grateful for any information regarding same. A You will find a full description, with drawings and all specifications, for a wireless telegraph outfit to transmit 100 miles, in our SUPPLEMENT No 1605, price ten cents.

(12143) J L. B says What chemicals can be compounded that will expand in cold weather and contract in hot weather? What minerals will expand in cold weather and contract in hot weather? A. You will find in Carhart's University Physics," Vol 2 page 24 the statement that Rose's metal contracts after the temperature reaches a certain point. This is an alloy composed of bismuth 2 parts, lead 1 part and tin 1 part. He also states that iodide of silver contracts regularly from 10 deg C to 70 deg C and that it reaches its point of maximum density at 116 deg C These statements we give you as they are given in the book referred to which we can send you for $1 75 postpaid Besides these we know no others

(12144) J L. B says I desire to construct storage cells in Crowfoot jars, using commercial sheet lead 2½ to 3 pounds per square foot About how many ampere minutes could I expect from each square foot of the oxidized plate if the cell is otherwise properly constructed? Would it be advisable to make the plates rough by deep scratching? What is the best concentration of acid to use? A. You will find in several of our SUPPLEMENTS plans and full descriptions of storage batteries of different forms We beg to refer you to Nos 845 1105 and 1433 which we will send for ten cents each You should not use smooth sheet lead The time of forming and the cost will be greatly increased We cannot tell what ampere minutes you will get per square foot The composition of the electrolyte is given in the descriptions in the SUPPLEMENTS referred to above

(12145) A. R. J says Kindly describe in your columns the process of making 72 deg and 76 deg gasoline Does it have to be charged with a natural or manufactured gas, or does the product itself contain the gas that makes it suitable for explosive motors? A Gasoline is produced by the simple distillation of crude petroleum of which it constitutes about 1.5 per cent It is the third product to come off at about 140 deg to 158 deg F the only lighter distillates volatilizing at a lower temperature being rhigolene which comes off at 113 deg and chymogene, from 113 deg. to 140 deg of both of which the percentage is extremely small The next heavier product is benzine or naphtha (which comes off all the way from 158 deg to 248 deg) Commercial gasoline however contains a good deal of the latter and runs up in gravity to 0.66 or 0.67 true gasoline being from 0.636 to 0.65 Gasoline is not charged with any other gas the explosive gas used in gasoline engines is a mixture of gasoline and air gasoline being very volatile i. e. evaporating rapidly its vapor being absorbed by air as water is by a sponge and the mixture being explosive The mixture of gasoline vapor with air is known as carburetion

(12146) J B says A train starts from rest and reaches its highest speed say 60 miles per hour in 5 minutes At the end of this time steam is immediately shut off and the train allowed to coast until it comes to rest How long will it take to come to rest coasting on a level track and friction alone retarding it? I maintain that the problem as it stands cannot be answered Am I correct? A Your problem is not solvable Neither the weight of the train nor the coefficient of friction are given Moreover the data you give are not concerned in the solution of the problem you state It matters not how long or by what force the train reaches its velocity When steam is shut off a train has a velocity of 60 miles per hour In what time will the train come to rest on a level track That is all you state toward the problem It is insufficient An engineer may assume data but these are not given in the problem as stated

(12147) N P W says Two cylindrical columns of wood iron or concrete have the same length and the same diameter and are identical in every respect save that one is hollow while the other is solid A claims that the hollow column will be stronger (with reference to any force tending to break or buckle it) and B claims that the solid one will be stronger Will you please oblige a subscriber by explaining in your query column plainly enough for the proverbial wayfaring man to understand it, which is right and *why?* A B is right The solid column will be the stronger, whether composed of wood iron or concrete or whatsoever material or whether resisting compression tension torsion or any other strain A's contention arises from a not uncommon misunderstanding of the well known rule that a tube is stronger than a solid rod *of the same weight* I. e. that a rod of one inch diameter will stand less endwise compression or torsion than *the same weight or volume* of metal would stand if made into a hollow column or tube of the same length and, say, two inches outside diameter

NEW BOOKS, ETC.

A Hand Book of General Instructions for Mechanics. Containing Useful Rules and Memorandum for Practical Men New York D Van Nostrand Company 1909 12mo., 328 pp. Price, $1 50

The primary object of the author in writing this book is to give the mechanic, who has not had educational advantages, a text book explaining established rules for calculating in a clear simple and concise way, making him familiar with the various technical terms and their meaning and to be in general such a course of instruction as to impart in a simple manner the required knowledge to enable him to read understandingly more advanced works. The plan of the book is excellent, and the illustrations and examples are particularly clear There is hardly anyone who has much occasion to use figures who would not be benefited by a perusal of parts of this book.

Precious Metals Comprising Gold, Silver and Platinum By T Kirke Rose A.R S M, D Sc New York D Van Nostrand Company 1909 12mo 295 pp Price $2

This is one of the volumes of the Westminster Series," which has proved such an excellent collection of technical literature The present volume deals with the methods of treating gold by the wet and dry process. The extraction of silver the refining and assaying of gold and silver ores, the assay of gold and silver bullion minting the manufacture of gold and silver wires, and a valuable chapter on platinum together with tables on the production of precious metals There has been room for a good book on gold and silver for some little time This book seems to fill the niche admirably

Motorman's Practical Air Brake Instructor By George R. Denehie Chicago Frederick J Drake & Co, 1909 18mo, 280 pp, leather back

This is a concise up to date treatise on the construction and operation of the different air brake equipments used in modern electric transportation The author has been at considerable pains, therefore to collect condense and compile all the latest available information bearing upon this most important subject of handling an electric car or a train of cars safely and at the same time economically The diagrams and illustrations are particularly clear Some of them are reproduced in colors The get up of the book however is not equal to another book on the same subject which we reviewed a short time since

Life of Sir Charles Tilston Bright, Civil Engineer By Charles Bright F.R.S.E. London Archibald Constable & Co Ltd New York D Van Nostrand Company, 1908 8vo 478 pp Price $4 50

In this book is incorporated the story of the Atlantic cable and the first telegraph to India and the colonies. In response to a number of suggestions in view of the fiftieth anniversary of the Atlantic cable Mr Bright has brought out an abridged edition of the biography of his father the original work having been written by Sir Charles Bright's brother and by his son There is probably no branch of engineering which lends itself so readily to a full sight of the world as that of telegraphy Therefore the present volume will appeal to the general reader only in a lesser degree than to the engineer the student and the historian Sir Charles Bright was as much a traveler as a scientist and even when engaged on the most trying cable venture in unhealthy climates, he invariably kept a neatly written record of the day's performance of what he had seen and learnt never retiring to bed without attending to his task The detail to be drawn upon is very large and the author has certainly made an excellent selection The story of the Atlantic cable is one of the most romantic in the history of science and it is gratifying that the biography of the pioneer should be written by his son

The Lead and Zinc Pigments By Clifford Dyer Holley M S Ph D New York John Wiley & Sons, 1909 12mo. 340 pp 85 figures Price $3 net

New pigments have come into use during the last ten years new processes have been developed for the manufacture of the older pigments new combinations of pigments have been worked out that have secured results hitherto unattainable Yet up to the time mentioned above except for short articles in some of the trade papers these improvements and innovations remained practically unnoticed. Since public attention has been directed to the paint industry by the enactment of the various State laws regarding the sale of paint materials several excellent American works have been written on this subject but the majority of them has been directed more particularly toward the compiling of analytical methods and data than to the manufacture and uses of the various pigments In this work the author has attempted to record the progress made in the United States in the manufacture of the more important pigments and hence but little space has been given to European methods and processes except for comparison, as they have been discussed in detail in various English and European works.

Manual of Steam Engineering, By W. H. Wakeman, New York and Chicago New York Belting and Packing Company.

Mr Wakeman's name is familiar to readers of the Scientific American Supplement, as well as to readers of technical journals in general as the author of many articles on engineering subjects. In this little book he has presented instructions, suggestions, and illustrations for steam engineers concerning the application to modern daily practice of the approved theory of steam engineering. Although the work is issued no doubt as an advertising pamphlet, it is essentially an engineering reference book containing data that are required in everyday practice, arranged in convenient form and with sufficient explanation to render the matter both interesting and instructive

Legal Notices

60 YEARS' EXPERIENCE
PATENTS
TRADE MARKS
DESIGNS
COPYRIGHTS &c.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO, 361 Broadway, New York
Branch Office 625 F St Washington, D C

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending November 16, 1909, AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Acetates, making H O Chute	939 960
Acetylene generating apparatus A Davis	940 457
Acetylene generator J Zauder	940 110
Acid from nickel-chlorid solution, recovering hydrochloric H L Wells	940 208
Acid phosphate and the like apparatus for handling J F Capers	940,583
Advertisement displaying apparatus, J T Roffy	940,281
Advertising card W O Holt	940,416
Air brake J W Hicks	940 314
Air ships and the like optical instrument for determining the direction of travel of O O Krell	940,8[illegible]

A Home-Made 100-Mile Wireless Telegraph Set
Read Scientific American Supplement 1605 for a thorough, clear description, by A. Frederick Collins, of the construction of a 100-mile wireless telegraph outfit Numerous adequate diagrams accompany the text. Price 10 cents by mail. Order from your newsdealer or from
MUNN & CO, Inc., 361 Broadway, New York

Aeroplanes and Motors
We are building monoplanes of the Bleriot cross-channel type. Delivery 8 weeks after receipt of order. Flight guaranteed. Price $5,000; one-third cash with order
We also build several kinds of light-weight aeronautic motors and propellers. Particulars and prices furnished upon application.
SCIENTIFIC AEROPLANE AND AIRSHIP CO.
Box 773, New York.

FOR GUNSMITHS TOOL MAKERS, EXPERIMENTAL & REPAIR WORK, ETC.
From 9-in. to 13-in. swing. Arranged for Steam or Foot Power, Velocipede or Stand-up Treadle.
Send for Lathe Catalog.

Established 1872.
1999 Ruby St., Rockford, Ill.

Pipe Cutting and Threading Machine
For Either Hand or Power
This machine is the regular hand machine supplied with a power base, pinion, countershaft, etc., and can be worked as an ordinary power machine or taken from its base for use as a hand machine. Pipe ⅛ in. to 1¼ in. diameter handled easily in small room. Illustrated catalogue—price list free on application.

6 Garden St., Bridgeport, Conn.

Two Good Books for Steel Workers

Hardening, Tempering, Annealing and Forging of Steel
By JOSEPH V. WOODWORTH
Size 6¼ x 9¼ inches. 288 pages. 201 illustrations. Price $2 50 postpaid
THIS is a practical work, treating clearly and concisely modern processes for the heating, annealing, forging welding hardening and tempering of steel, making it a book of great value to toolmakers and metal working mechanics in general. Special directions are given for the successful hardening and tempering of steel tools of all descriptions, including milling cutters, taps, thread dies, reamers, hollow mills, punches and dies and various metal-working tools, shear blades, saws, fine cutlery and other implements of steel, both large and small The uses to which the leading brands of steel may be adapted are discussed, and their treatment for working under different conditions explained also special methods for the hardening and tempering of special brands. A chapter on case-hardening is also included.

The American Steel Worker
By E. R. MARKHAM
Size 6¼ x 8 inches. 367 pages. 163 illustrations. Price $2.50 postpaid
THIS is a standard work on selecting, annealing, hardening and tempering all grades of steel, by an acknowledged authority The author has had twenty-five years' practical experience in steel-working, during which time he has collected much of the material for this book Careful instructions are given for every detail of every tool Among the subjects treated are, the selection of steel to meet various requirements, how to tell steel when you see it; reasons for different steels; how to treat steel in the making of small tools, taps, reamers, drills, milling cutters; hardening and tempering dies; pack-hardening; case-hardening; annealing; heating apparatus; mixtures and baths, the best kind, and why; and in fact everything that a steel-worker would want to know is contained in this book.
OUR SPECIAL OFFER: The price of these books is $2.50 each, but when the two volumes are ordered from us at one time, we send them prepaid to any address in the world on receipt of $4.00.

Home-Made Experimental Apparatus

In addition to the following articles, the Scientific American Supplement has published innumerable papers of immense practical value, of which over 17,000 are listed in a carefully prepared catalogue, which will be sent free of charge to any address. Copies of the Scientific American Supplement cost 10 cents each.

If there is any scientific, mechanical, or engineering subject on which special information is desired, some papers will be found in this catalogue, in which it is fully discussed by competent authority.

A few of the many valuable articles on the making of experimental apparatus at home are given in the following list:

ELECTRIC LIGHTING FOR AMATEURS. The article tells how a small and simple experimental installation can be set up at home. Scientific American Supplement 1551.

AN ELECTRIC CHIME AND HOW IT MAY BE CONSTRUCTED AT HOME, is described in Scientific American Supplement [illegible].

THE CONSTRUCTION OF AN ELECTRIC THERMOSTAT is explained in Scientific American Supplement [illegible].

HOW TO MAKE A 100-MILE WIRELESS TELEGRAPH OUTFIT is told by A. Frederick Collins in Scientific American Supplement [illegible].

A SIMPLE TRANSFORMER FOR AMATEUR'S USE is so plainly described in Scientific American Supplement 1572 that anyone can make it.

A ½ H.P. ALTERNATING CURRENT DYNAMO. Scientific American Supplement [illegible].

THE CONSTRUCTION OF A SIMPLE PHOTOGRAPHIC AND MICRO-PHOTOGRAPHIC APPARATUS is simply explained in Scientific American Supplement [illegible].

A SIMPLE CAMERA-SHUTTER MADE OUT OF A PASTEBOARD BOX, PINS, AND A RUBBER BAND is the subject of an article in Scientific American Supplement [illegible].

HOW TO MAKE AN AEROPLANE OR GLIDING MACHINE is explained in Scientific American Supplement [illegible], with working drawings.

EXPERIMENTS WITH A LAMP CHIMNEY In this article it is shown how a lamp chimney may serve to indicate the pressure in the interior of a liquid, to explain the meaning of capillary elevation and depression to serve as a hydraulic tourniquet, an aspirator, and intermittent siphon; to demonstrate the ascent of liquids in exhaustive tubes to illustrate the phenomena of the bursting bladder and of the expansive force of gases. Scientific American Supplement [illegible].

HOW A TANGENT GALVANOMETER CAN BE USED FOR MAKING ELECTRICAL MEASUREMENTS is described in Scientific American Supplement [illegible].

THE CONSTRUCTION OF AN INDEPENDENT INTERRUPTER. Clear diagrams giving actual dimensions are published Scientific American Supplement [illegible].

AN EASILY MADE HIGH FREQUENCY APPARATUS WHICH CAN BE USED TO OBTAIN EITHER D'ARSONVAL OR OUDIN CURRENTS is described in Scientific American Supplement [illegible]. A plunge battery of six cells a two-inch spark induction coil, a pair of one pint Leyden jars and an inductance coil, and all the apparatus required, most of which can be made at home.

SIMPLE WIRELESS TELEGRAPH SYSTEMS are described in Scientific American Supplements [illegible] and [illegible].

THE LOCATION AND ERECTION OF A 100-MILE WIRELESS TELEGRAPH STATION is clearly explained, with the help of diagrams, in Scientific American Supplement [illegible].

THE INSTALLATION AND ADJUSTMENT OF A 100-MILE WIRELESS TELEGRAPH OUTFIT, illustrated with diagrams, Scientific American Supplement [illegible].

THE MAKING AND THE USING OF A WIRELESS TELEGRAPH TUNING DEVICE, illustrated with diagrams, Scientific American Supplement [illegible].

HOW TO MAKE A MAGIC LANTERN, Scientific American Supplement [illegible].

THE CONSTRUCTION OF AN EDDY KITE. Scientific American Supplement [illegible].

THE DEMAGNETIZATION OF A WATCH is thoroughly described in Scientific American Supplement [illegible].

HOW A CALORIC OR HOT AIR ENGINE CAN BE MADE AT HOME is well explained, with the help of illustrations, in Scientific American Supplement [illegible].

THE MAKING OF A RHEOSTAT is outlined in Scientific American Supplement [illegible].

Good articles on SMALL WATER MOTORS are contained in Scientific American Supplement [illegible], [illegible], and [illegible].

HOW AN ELECTRIC OVEN CAN BE MADE is explained in Scientific American Supplement [illegible].

THE BUILDING OF A STORAGE BATTERY is described in Scientific American Supplement [illegible].

A SEWING-MACHINE MOTOR OF SIMPLE DESIGN is described in Scientific American Supplement [illegible].

A WHEATSTONE BRIDGE. Scientific American Supplement [illegible].

Good articles on INDUCTION COILS are contained in Scientific American Supplements [illegible], [illegible], and [illegible]. Full details are given so that the coils can readily be made by anyone.

HOW TO MAKE A TELEPHONE is described in Scientific American Supplement [illegible].

A MODEL STEAM ENGINE is thoroughly described in Scientific American Supplement, [illegible].

HOW TO MAKE A THERMOSTAT is explained in Scientific American Supplements [illegible], [illegible], and [illegible].

ANEROID BAROMETERS. Scientific American Supplements [illegible] and [illegible].

A WATER BATH. Scientific American Supplement [illegible].

CHEMISTRY OF SOLDERING AGENTS.

(Concluded from page 389.)

chloride preparations are very convenient in use and very reliable, causing the solder to adhere firmly Even when the surfaces to be joined are greatly oxidized, a good joint can be made by a skillful workman. In order to prevent the possibility of injurious after effects, it is customary to wash the soldered joint with zinc chloride solution. Cable joints made with the aid of zinc chloride were opened and examined after the same intervals of time that were allowed for the joints made with ammonium chloride Although the zinc chloride also penetrated between the wires the difference in the result was very great. The wires of the core were covered with a dry, wax like dark green coating, and a substance resembling pitch was found in places where the other ingredients of the zinc chloride soap had been decomposed by overheating, but junctions which had been traversed by strong currents for long periods showed no appreciable increase in resistance

The assertion that injurious effects are necessarily produced by hydrochloric acid separated by hydrolysis from the hygroscopic zinc chloride was also submitted to the test of experiment. Copper wires less than 1/250 inch in diameter were soldered together and the junctions were covered thickly with the zinc chloride mixture and inserted in an apparatus with which their resistance could be measured while a current was kept flowing through them In a few days the mixture became moist, but it quickly dried and assumed the wax like appearance described above The wires were exposed freely to the air, but observations continued through a long period revealed no deterioration of the joint

Hence it may be asserted, as the result of exhaustive researches continued for years, that zinc chloride is in every way superior to ammonium chloride as a soldering agent. The inference that ammonium chloride is safe because it is possible to obtain it unmixed with free acid, is a pure delusion, for the injurious action of ammonium chloride on metals is due, not to the comparatively harmless hydrochloric acid, but to the other causes mentioned above

The extraordinarily good practical effect of zinc chloride preparations, however, still requires explanation —Zeit. f. Ang Chemie.

SOUNDING THE OCEAN OF AIR.

(Continued from page 393)

mer, autumn, or winter Kites and balloons have been sent up from almost every quarter of the earth Perhaps the most recent of these investigations in an out-of-the-way quarter of the globe is the meteorological expedition to East Africa undertaken by the Royal Prussian Meteorological Observatory The expedition was conducted by Prof Berson and Prof. Elias. The chief object was to determine the origin of monsoons, an object which was not altogether attained, but on which much light was thrown An ultimate aim was the prognosis of the rainy season in East Africa and India. On the coast and from a specially chartered steamer on the lake, *ballons-sondes*, pilot balloons, and kites were sent up. The observations over the equator, in the center of the continent, showed very low temperatures at great heights, as did the expedition of Teisserenc de Bort and Rotch on the equatorial Atlantic, but with the difference that over the African continent there was a trace of the permanent inversion layer The vertical changes were as follows adiabatic decrease of temperature to 13,000 meters, between 13,000 and 15,000 meters a small inversion, and above 17,000 meters isothermal conditions Above the southeast monsoon the wind was south-southwest, and three times a westerly wind was observed between 15,000 and 18,000 meters, above the great equatorial current from the east which is supposed to prevail at all heights.

It was feared that a very large per cent

Peary's Own Story

Of the Discovery of the North Pole

Commander Robert E Peary has chosen HAMPTON'S MAGAZINE as the medium through which he will tell the world his own remarkable story of the discovery of the North Pole.

This is without question the greatest feature ever offered by any publication The whole world is tremendously excited—and is now profoundly interested—in the North Pole situation

Only by reading Peary's own story in HAMPTON'S can you ever know the facts As an intelligent man or woman you positively need to read this, the greatest adventure story of modern times It will be richly illustrated with hundreds of remarkable photographs, and will ppear during 1910 exclusively in

HAMPTON'S

ADMIRAL EVANS

In a New Series of Articles, the First of Which Deals With the Panama Canal

Admiral Evans' opinion of the Panama Canal is an especially valuable piece of analysis. He shows us our errors succinctly, gives us definite reasons why they are errors, and tells us how we may remedy these mistakes

His first Panama article will be published in January HAMPTON'S Other articles on other subjects will follow, making of the Evans series one of the most valuable contributions to national thought that the year 1910 will bring forth.

HAMPTON'S for 1910 will publish the biggest features that have ever appeared in any magazine Send HAMPTON'S as a Christmas gift to your friends!

of the balloons which fell on land would be lost, because of the nature of the country and the sparseness of the population, but on the contrary an astonishing proportion of them was recovered, owing to the keenness of vision of the natives, to whom a small reward was offered for every one returned

What has been the result of this international aerial sounding? It has been discovered that all over the earth the air is stratified in three more or less distinct layers The lowermost of these, the layer in which we live and which extends upward for two miles from the surface of the earth (at which height the freezing point is encountered) is a region of turmoil warm to-day and cold to-morrow This is the stratum of capricious winds, cyclones and anti-cyclones, of cool descending currents and warm ascending currents All our weather forecasting is at present based on what can be learned from the general circulation of the air in this lowermost layer

Above this first layer, which extends upward for perhaps two miles, begins the second layer, which is about six miles thick, and is less turbulent than the first. In it the air grows steadily colder and drier with increasing height. Temperatures as low as 167 deg below the Fahrenheit freezing point have been recorded here Whatever thermal irregularities there may be are caused by temperature changes on the surface of the earth and by the reflection of solar heat from clouds The wind blows always in the same easterly direction, and the greater the height, the more ferocious is the blast.

The last of all the layers thus discovered lies above this Originally revealed by Teisserenc de Bort and Dr Richard Assmann almost simultaneously it was first known as the 'isothermal stratum' because its temperature seemed to be stationary Later when it was found that the temperature, instead of remaining fixed gradually increased, it was rechristened the "permanent inversion layer" The height of the inversion layer has not as yet been determined It must not be supposed that, because its temperature rises it is much warmer than in the second layer As a matter of fact, its temperature must be placed somewhere between 122 deg and 140 deg below the Fahrenheit freezing point. This permanent inversion layer is puzzling in the extreme In passing from the second to the permanent inversion layer the wind is stilled to a breeze the velocity decreasing from 25 to 80 per cent. The air blows no longer in a steadily easterly direction, but almost as capriciously as it does at the surface of the earth Dryness, excessive dryness is another characteristic of the permanent inversion layer In summer time the permanent inversion layer begins at a height of about 7½ miles above the earth, the higher it lies, the colder it is the lower it lies, the warmer it is There is no bodily shifting up and down of warm and cold masses of air so that a current ascending from the lower level spreads out when it encounters the permanent inversion layer, just as hot air which strikes the ceiling of a room

Up to about 10 kilometers the decrease of temperature is almost adiabatic, then in the next 5 kilometers there is usually a rise in temperature of 8 deg to 10 deg C with isothermal conditions up to at least 26 kilometers The lower zone Teisserenc de Bort calls the "troposphere" and the upper one the 'stratosphere' The former is a region of violent atmospheric disturbances for it has been shown that cyclones do not extend above the cirrus clouds though anti-cyclones persist to greater heights and therefore the stratosphere is lowest in the cyclone and highest in the anti-cyclone and its level sinks from the equator to the poles The stratosphere is a region of interlaced currents and small vertical movements

Up to the height of the permanent inversion layer, the temperature falls at an average of one degree C. per 100

Instructive Scientific Papers
ON TIMELY TOPICS

Price 10 Cents each by mail

ARTIFICIAL STONE. By L. P. Ford. A paper of immense practical value to the architect and builder SCIENTIFIC AMERICAN SUPPLEMENT 1500.

THE SHRINKAGE AND WARPING OF TIMBER By Harold Busbridge. An excellent presentation of modern views fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER By N Monroe Hopkins. Fully illustrated SCIENTIFIC AMERICAN SUPPLEMENT 1500.

DIRECT-VISION SPECTROSCOPES. By T H. Blakesley, M A. An admirably written, instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No. 1493.

HOME MADE DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 161 and 600 contain excellent articles with full drawings.

PLATING DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them.

DYNAMO AND MOTOR COMBINED. Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 844 and 865 The machines can be run either as dynamos or motors.

ELECTRICAL MOTORS. Their Construction at Home, SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641.

CURIOSITIES OF THE SKY
By GARRETT P. SERVISS

AN intimate and authoritative description of the curious bodies and lights to be seen in the sky He sees these things, reads about them, and hears now and then of some wonderful new discovery—but he never knows quite what it is all about. This book will tell him—authoritatively, for its author is a distinguished astronomer The photographs include many taken at the Lick and Yerkes Observatories during the most recent investigations. The book is one to be recommended to all sorts of readers, whether they are scientifically minded or not.

Fully Illustrated from Photographs and Chart Drawings.

IMAGINATION IN BUSINESS
By LORIN F. DELAND

A DISCUSSION and analysis, from the business man's point of view, of the methods of business life, and the reasoning that underlies them By imagination in business the author means the power to comprehend the instincts and prejudices of human nature, and to depend upon human nature itself to carry them to success.

16mo, Cloth, 50 cents net

The VALOR of IGNORANCE
By HOMER LEA

THIS book is suited to the hour, and certain to arouse wide discussion Its object is to show the unpreparedness of the U. S. for war Mr Lea deals with conditions that render us liable to attack, and discusses a plan by which the Japanese might seize and hold the Philippines, Hawaii, Alaska, and California.

[illegible] F. per 183 feet). Because of the constant upheavals to which the air is subject in its lower levels, this average rate of temperature reduction as we ascend is not always observed. Sometimes it even happens that for a short distance the thermometer rises instead of falls, but ultimately the temperature drops at a uniform rate until it reaches a point lower than that recorded by any North Pole explorer

The three layers of air which have been discovered by kites and balloons intermingle but slightly; one floats upon the other as oil floats upon water Of the great ocean of air at the bottom of which we move and live, three-fourths lies below the permanent inversion layer All our storms, our clouds or dust are phenomena of the lower two layers.

Treatment of the Eye by X-Rays.

(*Continued from page 394.*)

cyclitous stages, a very moderate application of X-rays does not have an injurious effect upon the ocular tissues and is able, with the aid of local medication, to overcome the disease. In this connection I may cite a personal experience, in which one of my patients was afflicted with a serious ocular traumatism, perforation of the cornea, traumatic cataract, and plastic iridocyclite of fifteen days' standing. The case was brought to me for consultation on the 2d of February, 1907

The eye was hypotonous, vision was extinct, hardly a sensation of light being preserved The case seemed to be hopeless, and in despair I made, in the course of one week, four applications of X rays, extending from the 2nd to the 14th of February, and simply prescribed atropine.

On the 3d of April improvement was apparent, the eye resumed the normal tension, although there still remained perikeratic inflammation and only a very weak luminous perception.

A new radio-therapeutic treatment was effected the same day, and on the 5th of June all traces of the inflammation having completely disappeared a month previously, I was able to extract the cataract with complete success.

It is certain that one single case is not as safe to base conclusions on as is a series of observations on analogous cases I have always thought, however, as a result of my experience in this case that I would never have been able to obtain such a rapid improvement and radical cure without X-rays.

Since 1907 I have treated in this manner six cases of iridocyclite and a case of optic neurosis by the continuous rays In the four initial treatments I have never applied irradiation too strongly, since the very first case (cataract and leucoma) revealed to me the danger of repeated treatments. The treatment has been considerably diminished in duration, and the cure is effected more rapidly than by ordinary medication Irradiation of neurosis six times in the course of two months did not result in any improvement, but was terminated by optical atrophy

This personal experience corroborates the conclusions of Cook and of Coover regarding the discontinuous effects of X-rays. The observations reported by the latter apply to *intermittent* X rays, which seem, in those cases where they have been utilized, to have a particular efficacy upon processes of cellular regeneration.

The cases treated by Coover related to four ulcerous corneas, two iridocyclites, and three optical atrophies. The ulcers and the iridocyclites were cured in a few treatments, and as for the atrophies of the optic nerve, an improvement was achieved in one case after four treatments, in another after three treatments, and in the last case after seven treatments.

These really striking results, especially in cases as grave as optic atrophy, lead

(*Continued on page [illegible].*)

Ten Cents a Copy Three Dollars a Year

The Independent

A WEEKLY MAGAZINE FOUNDED IN 1848

A MAGAZINE WITH A HISTORY

Founded in 1848, The Independent has for sixty-one years maintained a high rank among the foremost American periodicals. It has championed causes which were once bitterly attacked, but are now universally accepted, such as the abolition of slavery and the higher education of women In its columns, the great questions of the day are discussed editorially and by outside contributors of authority

A WEEKLY NEWS REVIEW OF THE WORLD

The first eight pages of every issue are devoted to a summary of the events of the week thruout the world This boiled down information is the substance of the contents of a hundred newspapers and as many magazines. To read The Independent is to keep informed of the best that is being thought and done

ORDER BEFORE THE ADVANCE IN RATE

On January 1, 1910, the subscription price will be raised from two to three dollars a year To all names sent us before that date we will send the remaining issues of 1909 free and one full year in advance to January 1, 1911, for two dollars By accepting this offer you will obtain about sixty copies of a *High Class Illustrated Weekly Magazine* for a little over three cents an issue.

USE THE ATTACHED BLANK

THE INDEPENDENT, 130 Fulton Street New York

Enclosed please find Two Dollars, for which send me THE INDEPENDENT to January 1st, 1911, in accordance with your special offer

130 Fulton Street, New York

Durability!

Waltham Watches will last a lifetime or more, but get your watch started right. Buy from no one but a regular jeweler. Many little accidents may have happened to a watch

WALTHAM WATCHES

in transportation from the factory to store. Regular jewelers know how to find out and remedy such things, and they do before selling anyone a watch.

N. B.—When buying a Waltham Watch always ask your jeweler for one adjusted to temperature and position.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres., The Nat'l Co-op. Real Estate Co., Suite 368, Marden Bldg., Washington, D. C.

Inquiry No. 8918.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

ANYONE, anywhere, can start a mail order business at home. No canvassing. Be your own boss. Send for free booklet. Tells how. Heacock 178, Lockport, N Y

Inquiry No. 8987.—Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

WANTED $500.—This sum will build and patent new type airship; also three other valuable devices. Inventor take half. Engine builder to experiment with new rotary. For particulars address F. W. McLean, 811 Milam St., Shreveport, La.

PATENTS FOR SALE.

FOR SALE.—U. S. Patent No. [illegible], on work boxes. Compartment work box, useful to every woman at home or traveling. Full particulars on request. Thad Werstad, 420 Hudson St., Eau Claire, Wis.

Inquiry No. 8996.—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE.—Direct to manufacturers, Patent No. [illegible], granted July [illegible], on a ratchet monkey wrench. For further particulars address A. C. Jenrich, Columbia, Nev

Inquiry No. 8999.—For information regarding shoes not made of leather but similar to the same and are as durable.

THE SANBORN BAG LIFTER. A device to assist in handling bags of grain, cement, etc. Saves the sewers and avoids damage to bag. Sample sent free on request. H. & E. Sanborn, Portland, Maine.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc. to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete, with full set change gears to cut all size threads, 4 to 40 in. Price only $[illegible]. Address L. F Grammes & Sons, Allentown, Pa.

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

HELP WANTED

WANTED ENGINEER.—General knowledge mechanical electrical and practical engineer capable of handling construction work and establishing economical basis for power plants. Engineer Box 773, N. Y.

Inquiry No. 9022.—Wanted, to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

EDUCATIONAL.

CIVIL SERVICE EMPLOYEES are paid well for easy work; examinations of all kinds soon; expert advice, sample questions and Booklet 40 describing positions and telling easiest and quickest way to secure them free. Washington Civil Service School Washington, D. C.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany

MISCELLANEOUS.

"LIGHT, HEAT, MAGNETISM AND ELECTRICITY are all one and the same thing." If you want to know what they are, send fifty cents for a copy of this pamphlet to A. M. Howland, El Paso, Texas.

Inquiry No. 9028.—Wanted, to buy a washing machine that is run by a coil spring motor.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9034.—For manufacturers of machinery that could reduce stumps to kindling wood.

Inquiry No. 9036.—Wanted the address of the manufacturers of "Cyclo Ball Bearing Suspenders."

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

Inquiry No. 9042. Wanted the address of Furney Safety Razor Co

Inquiry No. 9043.—Wanted the address of the manufacturers of mirrors that are transparent when the light in the rear is stronger

Inquiry No. 9044.—Wanted to buy outfits necessary for agate polishing

Inquiry No. 9045. Wanted the address of the International Lumber and Development Co., manufacturers of hardwood.

HOW TO MAKE AN ELECTRICAL Furnace for Amateur's Use.—The utilization of 110 volt alternating currents for small furnace work. By N Monroe Hopkins. This valuable article is accompanied by detailed working drawings on a large scale, and the furnace can be made by any amateur who is versed in the use of tools. This article is contained in SCIENTIFIC AMERICAN SUPPLEMENT, No. 1182. Price 10 cents. For sale by MUNN & CO., Inc., 361 Broadway, New York City, or by any bookseller or newsdealer.

Three New Interesting Books

The Scientific American Boy at School

By A. RUSSELL BOND

12mo. 338 Pages. 314 Illustrations.
Price $2.00 postpaid.

THIS book is a sequel to "The Scientific American Boy," many thousand copies of which have been sold, and has proven very popular with the boys. The main object of the book is to instruct boys to build various devices and apparatus, particularly for outdoor use. The construction of the apparatus, which is fully within the scope of the average boy, is fully described and the instructions are interwoven in an interesting story, a feature which has assisted in making the "Scientific American Boy" so popular with the boys.

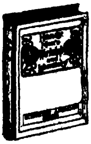
It takes up the story of "Bill" and several of his companions at boarding school. They form a mysterious Egyptian society, whose object is to emulate the resourcefulness of the ancients. Their Chief Astronomer and Priest of the Sacred Scarabaeus is gifted with magical powers, but his magic is explained so that others can copy it. Under the directions of the Chief Engineer dams, bridges, and canal-locks are constructed. The Chief Admiral and Naval Constructor builds many types of boats, some of which are entirely new. The Chief Craftsman and the Chief Artist also have their parts in the work done by the Society, over which Pharaoh and his Grand Vizier have charge. Following is a list of the chapters:

Chapter I, Initiation; Chapter II, Building a Dam; Chapter III, The Skiff; Chapter IV, The Lake House; Chapter V, A Midnight Surprise; Chapter VI, The Modern Order of Ancient Engineers; Chapter VII, A "Pedal Paddle-Boat"; Chapter VIII, Surveying; Chapter IX, Sounding the Lake; Chapter X, Signaling Systems; Chapter XI, The Howe Truss Bridge; Chapter XII, The Seismograph; Chapter XIII, The Canal Lock; Chapter XIV, Hunting with a Camera; Chapter XV, The Gliding Machine; Chapter XVI, Camping Ideas; Chapter XVII, The Haunted House; Chapter XVIII, Sun Dials and Clepsydras; Chapter XIX, The Fish Tail Boat; Chapter XX, Kite Photography; Chapter XXI, Water-Kites and Current Sailing; Chapter XXII, The Wooden Canoe; Chapter XXIII, The Bicycle Sled; Chapter XXIV, Magic; Chapter XXV, The Sailboat; Chapter XXVI, Water Sports, and Chapter XXVII, A Geyser Fountain. Index.

Handy Man's Workshop and Laboratory

Compiled and Edited by A. RUSSELL BOND

12mo. 467 Pages. 370 Illustrations.
Price $2.00 postpaid.



EVERY practical mechanic, whether amateur or professional, has been confronted many times with unexpected situations calling for the exercise of considerable ingenuity. The resourceful man who has met an issue of this sort successfully seldom, if ever, is averse to making public his methods of procedure. After all he has little to gain by keeping the matter to himself and, appreciating the advice of other practical men in the same line of work, he is only too glad to contribute his own suggestions to the general fund of information.

About a year ago it was decided to open a department in the Scientific American devoted to the interests of the handy man. There was an almost immediate response. Hundreds of valuable suggestions poured in from every part of this country and from abroad as well. Not only amateur mechanics, but professional men as well were eager to recount their experiences in emergencies and offer useful bits of information, ingenious ideas, wrinkles or "kinks," as they are called. Aside from these many valuable contributions came from men in other walks of life—resourceful men who showed their aptness at doing things about the house, in the garden, on the farm. The electrician and the man in the physics and chemical laboratory furnished another tributary to the flood of ideas. Automobiles, motor cycles, motor boats and the like frequently call for a display of ingenuity among a class of men who otherwise would never touch a tool. These also contributed a large share of suggestions that poured in upon us. It was apparent from the outset that the Handy Man's Workshop Department in the Scientific American would be utterly inadequate for so large a volume of material but rather than reject any really useful ideas for lack of space, we have collected the worthier suggestions, which we present in the present volume. They have all been classified and arranged in eight chapters, under the following headings:

I, Fitting up a Workshop; II, Shop Kinks; III, Soldering of Metals; IV, The Handy Man in the Factory; V, The Handy Man's Experimental Laboratory; VI, The Handy Man's Electrical Laboratory; VII, The Handy Man About the House; VIII, The Handy Sportsman; IX, Model Toy Flying Machines. Index.

Concrete Pottery and Garden Furniture

By RALPH C. DAVISON

Assistant Secretary Concrete Association of America

12mo. 196 Pages. 140 Illustrations.
Price $1.50 postpaid.

THIS work should appeal strongly to all those interested in ornamental concrete, as the author has taken up and explained in detail in a most practical manner, the various methods of casting concrete in ornamental shapes. The titles of the thirteen chapters which this book contains will give a general idea of the broad character of the work. They are entitled:

I, Making Wire Forms and Frames; II, Covering the Wire Frames and Modeling the Cement Mortar into Form; III, Plaster Molds for Simple Forms; IV, Plaster Molds for Objects Having Curved Outlines; V, Combination of Casting and Modeling an Egyptian Vase; VI, Glue Molds; VII, Colored Concretes; VIII, Methods Used for Producing Surfaces with [illegible]; IX, [illegible] of Aggregates; X, [illegible] Modeled by Hand and Inlaid with Colored Tile; X, Concrete Pedestals; XI, Concrete Benches; XII, Concrete Fences; XIII, Miscellaneous, Including Tools, Waterproofing, and [illegible].

The first two chapters explain a most unique and novel method of working pottery which has been devised by the author. The chapter on color work alone is worth more than the cost of the book inasmuch as there is little known on this subject, and there is a large and growing demand for this class of work. The author has taken for granted that the reader knows nothing whatever about the material and has explained each progressive step in the various operations throughout in detail. These have been supplemented with half-tone and line illustrations which are so clear that anyone can understand them. The [illegible] craftsman who [illegible] will especially appreciate the adaptability of concrete for pottery work, because it is a cold process throughout [illegible] away with the necessity of [illegible] necessarily with the firing [illegible]. The book is well printed on heavy [illegible] paper and [illegible] illustrations [illegible] show the unlimited possibilities of [illegible] in concrete.

MUNN & CO., Inc., Publishers, 361 Broadway, [illegible] us to hope that in a not far distant time we shall be able to cure this redoubtable affection, or may at least be able to prevent its evolution from the moment that the diagnosis has been made.

Time alone will assure that the cures related by Coover are permanent. The results so far achieved, however, deserve, in my estimation, our serious consideration.—Cosmos.

◆

Test of an American Helicopter.

In the recent Berliner-Williams helicopter trials at Washington, D. C., on the farm of Mr Emile Berliner, the two revolving-cylinder motors of Mr Berliner rested upon the platform of the machine, each being connected by its own countershaft to the main gear-wheels of the oppositely revolving propeller shafts, which are tubular and concentric Mr Williams also stood upon the platform, on the opposite side of the shaft from the motors The total weight lifted in this trial, including Mr Williams, was 610 pounds. The weight of the complete helicopter without him was 460 pounds, and the two motors, with countershafts, pinions, connections etc, weighed 248 pounds.

In previous trials each of the motors, installed singly had lifted the machine, with a little added weight upon an outrigger, for balance the thrust, or lift, being about 350 pounds, which compares favorably with previous experiments made by Mr Berliner last fall, when, with a single propeller of somewhat greater diameter and area, he got about the same results.

The two motors, which are duplicates, are of the star-shaped 5-cylinder, revolving type of 36 rated horse-power They were built specially for Mr Berliner and they had been overhauled, tested and worked into good running shape at Mr Berliner's laboratory

The helicopter, built by Mr J Newton Williams of Derby, Conn, about two years ago was first tried with a motor that proved to be too small for the work It was then connected by flexible shafting to the factory power to test the thrust of the propellers, which in a series of trials with from 13 to 19 measured B H P lifted from 250 to 430 pounds, and in a final trial in which the horse-power was not measured, a thrust was obtained of 560 pounds The machine was later taken to Hammondsport, N Y where an 8-cylinder 40 horse-power Curtiss motor was installed, and a number of trials made the motor lifting the machine with added weight totaling from 410 to 485 pounds but not being equal to lifting the weight of an average-sized man

In this last trial at Washington the blades of the propellers had been enlarged, increasing their diameter from 16 feet 8 inches to 18 feet 8 inches and increasing their area from 64 to 80 square feet. This increase of superficial area of the propellers increased the general efficiency of the machine, as the greater lifting surface gave a greater resultant lift per unit of horse-power, and the reduced revolution speed of the propellers, due to increased resistance gave a reduced revolution speed to the motors, which, with the transmission used seemed to give them greater efficiency

The propeller speed was 120 R. P M, while the speed of the motor was 900 R. P M

Mr Williams expects to have a 7 cylinder motor built of the same revolving type, and of 50 per cent more power, and will also build a helicopter on about the same lines, but of larger size and lighter construction.

The completed machine will have a parachute to retard the fall in an emergency, and its dirigibility is assured by very simple controlling devices, which are now being patented.

◆

It is regrettable that the Lighthouse Board has changed the name of the buoy marking the historic spot where the ironclad "Merrimac" went down after her defeat by the "Monitor." "Merrimac wreck buoy 23" will now be called "Channel buoy 23."

MEN WANTED
1800 men average $6.92 profit per day
Selling "WEAR-EVER" Aluminum Specialties
Half of these men had no previous experience. Work made pleasant by our 112 page Instruction Book. No domiciliary canvassing. Let us show you what others have done. Address

The Middle West Number of the SCIENTIFIC AMERICAN

On December 11th, 1909, the Scientific American will issue a number devoted entirely to the wonderful Middle West region of the United States, a number which will set forth broadly and lucidly not only the agricultural interests of that region but also those larger engineering undertakings which are destined to transform the Middle West, in part at least, into a manufacturing territory

With that object in view the Middle West Number will publish articles on the following subjects

I. The Chicago and Gulf Waterway —An illustrated description of Chicago's drainage canal, an engineering work which stands without a parallel in the world.

II Chicago as a Railroad Center.—Chicago is the greatest railroad center in the world

III. The Wonderful Grain Trade of Chicago.—Chicago is an enormous wheat bin, into which much of the grain raised in the middle West is poured.

IV Shipping on the Great Lakes.—Most of the iron ore that is now smelted in Pennsylvania is mined in the middle West. To transport it to the blast furnaces of the East at a cost which will enable American steel makers to compete with foreign steel makers, it has been necessary to devise a new kind of lake transportation. Ships of 10,000 and 12,000 tons burden have been constructed which convey ore at small cost through the Great Lakes, and which are without a counterpart anywhere in the world.

V. The Handling and Shipment of Iron Ore.—The above-mentioned fact that iron ore is mined in the middle West and smelted in the East has necessitated not only the construction of special freight-carrying steamers, but also the designing of special machinery for loading and unloading the ore from the steamers.

VI Freighting on the Mississippi —Freighting on the Mississippi is a more important industry than most of us may realize

VII. The Steel Industry One of the greatest steel plants in the world is that which has been built at Gary

VIII. The Freight Subway System of Chicago. —Chicago can boast of a rational system of handling freight by means of subways.

IX The Water Supply of Chicago.—Chicago's source of water is Lake Michigan The city is supplied with water by means of a tunnel which extends two miles out into the lake.

X. Reclaiming Arid Lands. The United States Government has under way many irrigation projects for the purpose of reclaiming lands which are arid but which will blossom if properly watered

XI Harvesting the Grain of the Middle West. Farms that cover not acres but square miles crops that aggregate not simply bushels but car-loads, have rendered it necessary to plant and harvest on an unprecedented scale in the middle West The ingenious agricultural machinery which has been designed to cope with these peculiar conditions is described and illustrated

The Middle West Number will be more than twice the size of the regular SCIENTIFIC AMERICAN. It will be lavishly illustrated It will be contained in a colored cover which strikingly depicts Chicago's grain elevators at work. Order from your newsdealer or from

A DECISION UNDER THE GERMAN-AMERICAN PATENT TREATY

In nearly all European countries a patentee incurs a *forfeiture* for not working his patent within a certain statutory period In Germany and some other countries this period is three years from the date of the patent's issue The United States, on the other hand, has stimulated invention by more liberal laws and imposes no obligation whatever on the inventor to manufacture his invention As a result a German inventor who takes out a patent in this country receives better treatment here than in Germany The status of a foreign patentee is therefore difficult to define When an American inventor discloses a secret, his country grants him a monopoly for a limited period as a reward Once disclosed, all the world is informed of the invention so that a certain injustice results from the fact that he may not be able to comply with the compulsory clauses of German and other foreign patent statutes. A man with more money than he has can thus take advantage of the situation after the expiration of the statutory period of grace The only advantage to a foreign country in granting a patent on an invention which has been patented here is that we in our turn are willing to accord the same rights to citizens of that foreign country It is therefore unfair for us to grant more to foreign inventors than American inventors receive abroad, particularly in view of the fact that no direct benefit is to be obtained from our award for a secret already disclosed

The only solution of the problem is to be found in reciprocity treaties. Such a treaty has been in force between Germany and the United States since August 1st By its terms American inventors are absolved from working their patented inventions in Germany within three years from the granting of the German patent. Heretofore failure to comply with this obligation would result in the loss of the German patent if an action for revocation were brought The new treaty provides in effect that the working of a patent in the territory of one of the contracting parties shall be considered as equivalent to its working in the territory of the other party Hence, an American citizen who works his United States patent in the United States will no longer be required to work his corresponding German patent in Germany in order to avoid forfeiture of his German patent Moreover, since reciprocal rights are now granted by Germany, it would seem that an American inventor who takes out a patent in Germany ought to stand before a German court exactly as he would before an American court so far as forfeiture is concerned In other words, since the United States does not compel him to work his patent, his German patent ought to be good whether he works his American patent or not

A decision has just been handed down by the Imperial Supreme Court of Germany which construes the treaty from the German point of view and which is so liberal in its conclusion that the treaty may be regarded as retroactive in a measure, so as to apply to unexpired patents granted before the treaty became operative. The facts of the case are not all before us, but from what we may glean from press dispatches it would seem that the case involved the forfeiture of a patent which was taken out in Germany by the German branch of an American house before the treaty was signed and which was not worked within the statutory period of three years An action brought to revoke the patent resulted in a forfeiture The present decision the result of an appeal reverses the judgment of the lower tribunal and holds that the patent was not forfeited Before the decision was handed down by the higher court the German branch had transferred its title to the American house but whether this had any effect on the decision we are unable to state because the decision is not before us. Indeed, the status of the German branch is not at all clear At all events, the decision is highly favorable to American inventors and places the German patents of American manufacturers on a most substantial footing.

THE CHERRY MINE DISASTER.

Now that the wave of newspaper frenzy has passed, there may be some of a scientific turn of mind who are anxious to know the real facts of the terrible disaster at the Cherry coal mine

Two large veins in this mine, at three and five hundred foot levels, are good producers, levels known as the 'second' and "third workings." The first is not worked. When the fire was discovered at or about 3 P M on Saturday November 13th, there were upward of three hundred and fifty men in the mine a force about equally divided between the second and third veins Coal was being hoisted from the third to the second level by means of a cage in the ventilating shaft, which is located about three hundred feet from the main shaft At the second level the coal was transferred to the main shaft, and from there hoisted to the tipple The main shaft extends to the third working but it is stopped at the second level by a false floor The cage in the ventilating shaft is operated by a duplex cylinder engine near the mouth at the surface. It never travels to the top of the ground and the engineer controls it only by pressure-bell signal At the main shaft there are two cages whose cables are run to opposite sides of the hoisting drum so that one is raised while the other is lowered. The men of course, take the same course as the coal in going and coming

Without doubt, the signal system at the main shaft is responsible for several lives The engine room of the main hoist is located about one hundred feet from the mouth of the shaft From the engine room a tube runs to the mine, with branches to each of the galleries At the different landings a small air pump is located The stroke of the piston in the pump compresses the air in the tube and causes a small hammer in the engine-room end to strike against a gong The gong is rung once for each stroke of the hand pump at one of the mine landings. A man in the cage obviously cannot direct the movement of the hoist After the engineer has been signaled to haul up the men in the car can give no further signals This arrangement was responsible for the loss of some life

At the ventilating shaft there is located a large-capacity fan which normally runs to deliver air down the shaft at a few ounces pressure. The foul air and gases are then forced up the main shaft in a strong breeze In case of fire it is customary to reverse this fan, in order that fire will not be pushed out into the main shaft where the men are attempting to escape and a signal is arranged to be given from the mine for such an emergency In this particular mine however, where the men must use both the ventilating shaft and the main shaft, the reversal of the fan simply cut off those seeking escape at the former in favor of those at the latter

It is not known who gave the order to reverse the fan but the signal came from the mine The fire had been discovered in the mule barns on the second level between the two shafts and men had begun to come up from the third level to the second, and to make their way over to the main shaft to join those from the second level to be raised to the surface The fan was blowing the fire toward the main shaft. The flames reached the dust-covered pine timbers of the structural work, when the reversal of the fan drew the flames toward the air shaft, thereby setting fire to the timbering there as well Upon the reversal of the fan the main shaft was cleared for a time. Although the cages were bringing up miners on each trip some four men decided to go down and assist the rest in getting to the shaft This was a mistake, for after the trip down, the would-be rescuers were as badly off as those whom they might have been able to save After three or four trips down, and with the rescuers' cage at the bottom the engineer received a bell to hoist away He had started the cage upward when he received a signal to stop, then to lower, then to hoist, then to stop and lower Finally there came a signal to stop The engineer waited in vain for another bell, and after about fifteen minutes he was forced by threats to raise the cage When it reached the surface, it was red hot and the men in it were all dead. The signal arrangement described was directly responsible for the loss of these lives When the men in the cage were ready to be hoisted, one of their number had reached to the pump and given the necessary signal The cage had then started upward, and had proceeded only a few feet when another miner running toward the shaft, saw it and reaching the signal on the landing, brought it back. After he had been taken on board and the cage again started upward a second late arrival repeated the performance By this time the fire had overtaken them, and rendered further signaling impossible The cage should have been kept moving, but the engineer was bound by fixed rules and, moreover, had no way of knowing the conditions at the bottom of the shaft.

The only course left was to seal the shafts and smother the flames, which was done by means of steel rails, planks, and sand. On Sunday morning the seal was broken, and the fire found to be only smoldering. At this time it would probably have been feasible to have entered the mine, full of smoke as it was, with the assistance of oxygen helmets. Once down, it would have been a simple task to have quenched the fire with a good stream of water Instead, the fan was foolishly started, with the idea of clearing the mine of smoke and gas. Common sense could have foreseen but one result. The mine was quickly in flames again, and the hope of saving any of the men who might still be alive was given up

On Thursday several descents were made by way of the ventilating shaft, but the mine remained practically sealed until Friday when the first bodies were taken out Gases or "black damp" offered few obstacles On Saturday, one week after the accident, the miners who had walled themselves up in some of the galleries of the second vein were taken out very little the worse for their long confinement, a living rebuke to the experts of the State Mining Commission, and of the technologic branch of the U. S. Geological Survey, who had declared positively from the first that there were no live men in the mine, and that a day or two more or less made little difference

As a result of the Cherry disaster, the subject of safeguards for mines will receive a great deal of attention It seems many improvements in general mining practice can be made if the lessons taught at Cherry are well learned.

We would make the suggestion that several of the worked-out chambers in each level of a coal mine be fitted up with supplies, food, and water, to last some length of time, that airtight doors of steel be provided, and that pipes from the air compressors on the surface be led to these rooms by way of the shafts. A small amount of air under a few pounds pressure would serve to keep men alive for days and weeks. The expense of such an arrangement would be little

HIGH AND CROSS-COUNTRY FLYING ABROAD

Since the daring high flights of Orville Wright at Potsdam and of Count de Lambert above the Eiffel Tower at Paris (which was also made with a Wright biplane), the other foreign aviators have been striving to outdo these feats of high and cross-country flying. At the aviation meetings in England recently, army officers made determinations with their theodolites of the height reached, this being the first occasion when the altitude of an aeroplane has been officially observed in this way The greatest height reached there was 720 feet, attained by Paulhan on his Farman biplane, but this record was considerably beaten by the same aviator at Mourmelon, France, on the 19th and 20th ultimo. On the first of these two days, M Paulhan, in a 10-minute flight in a wind said to be of 20 miles an hour velocity, rose to a height of 369 meters (1,210 feet), while Latham, on his bird like "Antoinette" monoplane reached 410 meters (1,345 feet), thus making a new height record for a single-surface aeroplane Not to be outdone by his rival however, Paulhan the next day made a new official record of 500 meters (1,640 feet), thus duplicating the height reached unofficially by Orville Wright at Potsdam Besides this, he made a 55-minute flight from Mourmelon to Chalons and back, a distance of about 37 miles, in 55 minutes, or at an average speed of 40 miles an hour In this flight he attained a height of nearly 1 000 feet, and at its termination glided to earth with his motor stopped from a height of about 700 feet. This method of descent, which is that usually followed by Paulhan, is far less dangerous than was that employed by Orville Wright at Potsdam, when he descended at a terrific speed in one-third the time it took him to ascend, and with his motor throttled only slightly, owing to his inability to throttle it down completely He did not stop the motor, owing to his fear of alighting upon women or children (who were liable to run out and let the aeroplane fly over them) in case his machine was not completely under control.

Although Latham has not yet beaten Paulhan's record for height, he nevertheless made a sensational cross-country flight on November 23rd from Chalons to Berru, in order to attend a hunting party. At the appointed hour the monoplane appeared like a swift bird in the sky, circled twice around the field, and alighted in front of the hunting lodge. Latham, gun in hand, jumped out of his machine. After a successful hunt, he returned to Chalons in the monoplane. In addition to these two cross-country flights in France and his flight across Berlin last September, Latham also holds the record for flight in a strong wind as a result of his daring performance at Blackpool, England, on October 22nd, when he flew twice around the course in 10¾ minutes in a strong gusty wind which, according to the registration of a recording anemometer, had a velocity at times as high as 40 miles an hour.

[illegible] of the [illegible].

[illegible] River project of the [illegible] Service in Arizona, at the [illegible] per cent of com[illegible].

What is said to be the largest belt in the world has just been completed. It is 340 feet long and 6 feet wide; it has three-ply thickness, and the cost was $5,000; 540 hides were used in the construction.

In round numbers there are 1,250 street and interurban railway companies in America, with a total of 38,000 miles of single track and 75,000 passenger cars. The total number of passengers carried annually is 10,000,000,000, and the gross annual income is $440,000,000.

The monthly report of the passenger-train performance on the New York steam railways for August last shows that 65,312 trains were operated, of which 87 per cent were on time at the division terminals, as against 61,397, or 75 per cent, which were on time in August, 1908.

Continued rains throughout the Isthmus of Panama has resulted in two slides, which occurred in the Culebra cut. The occupants of the houses near by have been removed to safer quarters. The Chagres River has flooded large tracts, and in a number of places the railroad is under water

The French War Office has recently acquired an automobile which is capable of being instantly changed from a land to a water machine. It has a speed of 40 kilometers on land, and 12 kilometers while in the water It can carry four persons, and is actuated by a 14-horse-power motor.

In an address before the American Civic Association, Mr. Herbert M. Wilson, chief engineer in the United States Geological Survey, places the annual damage and waste by smoke in the United States at $500,000,000 in the large cities alone, or about $6 to each man, woman, and child of the population.

A gasoline car is being given a trial on the road leading to the estate of the late Mr Harriman at Arden. The experiment is considered an important one, and it is thought results will prove that the gasoline-propelled car can be used as economically as one propelled by steam on short branches.

Suit was begun in Pittsburg on November 16th by the Krupp steel-manufacturing interests against an American steel-manufacturing concern for infringement of certain patent rights involving the manufacture of armor plate. The testimony relative to the patents used by the defendant concern was given behind closed doors.

The first boats built especially for the 1,000-ton barge canal arrived in New York a short time ago. They consist of a steam-power boat and five barges. They brought down on their first trip a cargo of 83,000 bushels of oats. At present there are only 2,000 canal boats of all sizes in New York State, and of these only 400 are of the first class, even these are rapidly wearing out.

A curious test was recently made on a manganese-steel bank safe by experts. The safe withstood fifteen charges of nitro-glycerine. The explosion of the last charge threw the safe over backward, and blew off the outer layer of the door. It was found that the inner part of the door, however, was but little affected. Unless some more effective method can be tried for opening safes of this type, they may be considered for the time being to be burglar-proof.

An article in Le Génie Civil states that seventy-eight electric furnaces now exist in the steel works of the world, of which thirty-five are on the induction and forty-three on the arc principle. Fourteen are Kjellin furnaces, eleven Stassano, ten Röchling-Rodenhauser, three Elektrometall Society (Sweden), and one each Colby, Hiorth, Keller, Schneider, and Wallin. There is a steady and marked tendency to increase the capacity of these furnaces, some of those already constructed holding as much as eight to ten tons.

The first regular passenger train through the Pennsylvania Railroad tunnels from Harrison, N. J., under the North River, across Manhattan Island, and under the East River to Long Island City, made the trip on November 18th. This announced the practical completion of one of the most important achievements in American railroading. As the tunnels have not been electrified as yet, the train was pushed through the tunnels by a locomotive. The train was filled with officials, and time was allowed to thoroughly inspect the work, which will have cost nearly $160,000,000 by the time all is completed. All the tunnels will not be open to the traveling public for several months to [illegible] between the Manhattan [illegible] and Long Island will be open to the [illegible] and that the whole tunnel will be open by [illegible] 1910.

ELECTRICITY.

The Chicago City Council has recently passed an ordinance requiring that in cases of a delay of over ten minutes on surface or elevated lines, fares must be refunded to the passengers.

Our Vice Consul General in Calcutta calls attention to the opportunities in India for the sale of small electrical installations in country places. He describes a small plant consisting of a dynamo driven by an oil engine and a storage battery, which is arranged to operate thirty lights and eight electric fans. He urges American electric companies to investigate the subject, as there is a large opening for such installations

The Spiez-Frutigen section of the Bernese Alpine Railway is about to be electrified The power will be obtained from a pair of turbo-generators at Spiez, generating 6,400 horse-power at 15,000 volts. The line will be provided with two locomotives and three motor cars, each car weighing 58 metric tons The motor cars will be required to take a load of 240 tons up a grade of 1.55 per cent, or a load of 160 tons up a 2 7 grade at about 30 miles an hour

A very convenient device for cleaning incandescent lamp globes that are out of reach has recently been put on the market. It consists of a pole provided with a pair of rubber-covered jaws, which may be closed onto the lamp by pulling a cord The lamp globe may then be unscrewed from its socket. The jaws remain closed until a second cord has been pulled In cases where the lamps do not project vertically downward the device is applied to a pole, which is jointed so that the jaws may be inclined to fit over the lamp

Central Park, New York, is to be illuminated with 1,477 electric lamps in place of the 400 gasoline lamps now in use. Three reasons have been given for this change. In the first place, the park is insufficiently illuminated at present, secondly, the use of gasoline has resulted in the destruction of grass around each lamp post, due to dripping or leakage, and finally, the lamplighters have worn paths across the turf from one lamp to another The use of electricity will not require unsightly overhead wires, as the circuits will be contained in armored cables placed underground

The introduction of tungsten lamps is doing much to advance the use of electricity on farms. It is possible for the farmer with a small plant, driven either by a gasoline engine or by damming a small stream to obtain sufficient current to light his house and barn with this economical type of incandescent lamp The use of electricity on the farm, by the way is growing and, as pointed out by the Electrical World, farmers will in time come to consider electricity a necessity Then it will be found profitable to establish central generating stations for farming districts to take the place of the small individual plants now being installed

Experiments have been made in Switzerland showing that the higher altitudes provide exceptionally favorable locations for wireless telegraph receiving stations Messages coming from points within a radius of two thousand miles have readily been picked up in the Alps. This is probably due to the fact that there are few intervening objects between these elevations and the sending stations which would be apt to interfere with the Hertzian waves. It has always been difficult to send messages across the Alps, or even from one part of Switzerland to another over the high altitudes for the reason that the mountains absorb much of the energy

Action has not yet been taken by the Chicago City Council on the question of enforcing the electrification of Chicago's railroad terminals. The employees of the railroad are raising objections to the proposed ordinance. They point to the fact that electrification would increase the danger to railroad men, particularly in the freight yards, claiming that it would be impossible to switch cars without having men standing on the car roofs, and here they would be liable to come in contact with sagging trolley wires, while if the third-rail system were used it would always be a source of danger even though protected One of their principal objections, however, is that they would be in danger of losing their positions.

According to an article in Harper's Weekly, one cent's worth of electricity will make four cups of coffee, or cook a steak, or boil two quarts of water, or make a Welsh rarebit, or operate a 7 inch frying pan for twelve minutes, or an electric griddle for eight minutes, or an electric broiler for six minutes, or run a sewing machine for three hours, or an electric flat-iron for fifteen minutes, or a luminous radiator for eight minutes, or a heating pad for two hours, or a foot warmer for fifteen minutes, or a massage machine for four hours, or a curling iron once a day for two weeks, or a dentist's drill for an hour and a half, or an electric piano player for an hour, or vulcanize a patch on an automobile tire, or keep a big glue pot hot for an hour, or brand electrically 150 hams or raise a passenger elevator five stories a minute or raise 250 gallons of water 100 feet high, or raise ten tons 12 feet high in less than one minute.

SCIENCE.

King Victor Emmanuel recently visited the Baths of Diocletian, which it is proposed to isolate and restore on the occasion of the celebration of the fiftieth anniversary of the proclamation of United Italy The king has approved the project to repristinate the plan of Michael Angelo, who adapted the ancient ruins to the present church instead of building a new façade as was originally intended Thus the ruins will remain untouched The sum of $160 000 has been provided to meet the expense of the necessary work.

The Duke of the Abruzzi has presented the "Stella Polare,' the whaler which he purchased for the expedition to Franz Josef's Land to the Ricreatorio Navale di Roma, an institution founded by the Naval League with the object of training young men both for the merchant marine and the royal navy. The 'Stella Polare," which is at present at Spezia, soon will be brought up the Tiber to Rome and will be anchored off the port of Ripagrande, where it will be used for training students of the Ricreatorio

A physician who has made a careful study of the effects of roller skating has shown that excessive indulgence in this sport frequently results in flat feet, defective development of the leg muscles, and impairment of the gait and carriage of the body Roller skating is especially injurious to growing children, whose muscles, bones, and joints are still in process of development The muscles used in walking, especially those of the feet remain inactive in roller skating, while other muscles are overworked Hence the body becomes more or less deformed especially in the case of young girls who fail to acquire their normal grace and beauty of form

The American Museum of Natural History has acquired about two-thirds of a skeleton of a ceratopsian, a newly discovered species of which the triceratops or dinosaur is a member The skeleton s size is about the same as the triceratops, which it resembles generally The discovery of this remarkable prehistoric animal was made by Barnum Brown of the museum staff who has just returned with an expedition from Montana. The Laramie formation in which the skeleton was found is estimated at 3,000 000 years This species of dinosaur was an herb eater and walked on four feet Its measurements if it is the same as a triceratops, should be about twenty three feet long and about seven feet wide.

Within the next few months radium will be manufactured in London Hitherto the world has had to depend upon Continental laboratories for its radium The new factory has been constructed according to the requirements of Sir William Ramsay, who has devised a method of radium extraction which will, it is claimed, enormously reduce the time now needed for the elimination of the non radio-active elements of pitchblende The more elementary properties of radium in the domain of medicine are becoming fairly well known and hopes are not yet abandoned that by its immediate means one at least of the great and fast-growing curses of modern life may ultimately be arrested It is, in the first instance, for therapeutic purposes that the new English manufactory is now being built.

Lendenfeld has made moving pictures of the flight of insects, with exposures of 1/42 000 second. Cranz has made a kinematographic study of the action of weapons and projectiles employing for illumination electric sparks of a duration of one ten millionth of a second and obtaining pictures of 400 successive phases of the operation of the firing mechanism of an automatic pistol although the entire operation occupied only about one-tenth of a second On the other hand, Kohler has made a series of Roentgen ray photographs of the movements of respiration the time of exposure of each photograph being 15 seconds, during which the breath was held The photographs, after suitable reduction, were joined together in a continuous strip which when used in connection with a kinematographic projecting apparatus, gave a moving picture of the respiratory process.

About two years ago Rutherford discovered that charcoal made from cocoanuts possesses the property of absorbing at ordinary temperature and retaining for a long time the gaseous emanations of radium thorium, and actinium Dr Shober of Philadelphia has attempted to make practical use of this property for medical purposes, especially for the internal application of radio-activity Attempts to use water as a vehicle of the emanation had failed, because water loses its radio-activity very rapidly The experiments with cocoanut charcoal have given very satisfactory results, both qualitatively and quantitatively The charcoal is entirely neutral and permanent, and can be administered internally with perfect safety It can be made very easily and cheaply, has 200 or 300 times the radio-active absorptive capacity of water, and retains its activity for at least two weeks. The administration of the new preparation is very convenient and affords the possibility of producing, in equal or greater degree, all the effects of radio-active spring water

AN ELECTRICAL HOUSEHOLD

BY JACQUES BOYER.

The house which has just been fitted up in the heart of Paris by M George Knap, of Troyes, is the last and most perfect illustration of modern comfort, and although a household of this character is not within the reach of everyone its originality well merits description

After having opened the door, by pressing a button, and confided to the telephone the object of our visit, we are conducted to the dining room If a meal is being served, we are surprised to see no waiter moving around the room The servants remain in the kitchen, and send up every dish at the proper moment. In the dining room is a switchboard with electrical measuring instruments and the necessary keys and commutators The function of each key is inscribed above it in order to diminish the chance of error and a large bipolar commutator allows the switchboard to be cut off from the illuminating circuit Various combinations of lights can be used according to circumstances A large ornamental piece and dishes of fruit adorn the central part of the table, which is strewn with roses in which tiny electric bulbs are concealed This central portion is surrounded by an oval groove which leads to the two silver-plated doors which cover the entrance to the electric elevator The area devoted to the plates and other utensils of the guests is bounded by low parapets of glass and silver Below the table nothing appears except two nickel plated bars which serve to guide the elevator, which is placed in the basement directly under the dining room. One of these bars supports the mechanism which operates the elevator and the crescent-shaped doors above it. On the table, beside the host, are four push buttons When all the guests are seated, the host presses the white button, which causes a little drum to beat in the kitchen Immediately the doors of the elevator shaft open, the soup tureen ascends to the table, and the doors close and conceal the opening By pressing a red button at the right or left, the dish is caused to travel around the table in the corresponding direction It is arrested at any point by removing the finger from the button Other dishes are served in the same manner The function of the fourth button is to cause the dish to rotate, in order to assist the guest in helping himself. When the course has been thus served, the dish is brought back to the elevator by the operation of the buttons, and the drum in the kitchen is caused to strike twice Immediately the elevator doors open, and the elevator descends to the kitchen, whence it returns with the next course, after the plates have been changed

Let us now take a look at the clean and neatly furnished kitchen. The electric range is incased in wood and marble, so that it resembles a buffet. Attached to it are a switchboard, an electric clock a rheostat by which the strength of the current and the heating effect are varied, and an ammeter which measures the current employed in cooking each dish. The range contains four separate electric heaters of polished aluminium, which can be operated singly or simultaneously By means of the electric clock, every dish can be cooked to precisely the proper degree. If, for example, a fowl is placed in the electric oven, it is known from M Knap's experiments that it will require 30 minutes to roast it by radiation The electric contact of the clock is, therefore, set at the figure 30, and at the moment when the desired number of minutes have elapsed, the current is automatically cut off, and an electric bell advises the twentieth century chef that his fowl is cooked to a turn.

Milk is automatically drawn into the stew pan, sauces and cakes need merely to be placed on or in the range, and the current does the rest. The cook can go off and smoke a cigarette without risk of burning his sauces or pastry This method of electric cooking would not be very expensive when the current can be obtained from water power or from the waste power from a large motor

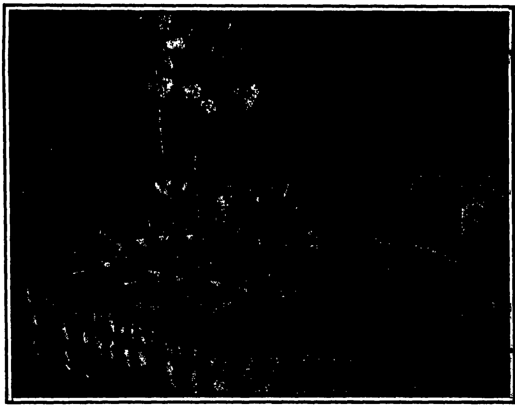
The electric kitchen contains a rotating table, on which are placed machines for chopping meat, churning cream, washing dishes, and other apparatus, driven by a small dynamo. Some curious phenomena may be observed in this electric kitchen. For example, eggs are "boiled" without the use of water, and, in contrast to what occurs in cooking with wood, coal, or gas, a fowl begins to cook at the center, and the skin is not browned until the cooking is finished M. Knap asserts that this method of cooking does not dry out the meat, and gives it a particularly agreeable flavor.

Near the kitchen is a laundry with electric washing machines, electric drying stoves, electric irons and ironing machines, etc.

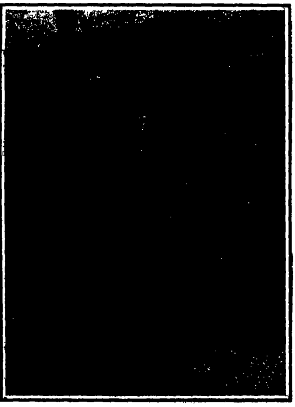
In the bedroom we find other novelties. The hot-

Arrival of the dish on the table.

The electric kitchen.



The electric dining table.



A bedroom in which breakfast is served by electricity.

AN ELECTRICAL HOUSEHOLD

water bag or bottle is replaced by an electric bed warmer containing a small lamp, which is operated by compressing a bulb which hangs above the sleeper's head. In the morning the occupant of the room has only to press a button, and an elevator concealed in a small table will bring him his breakfast and his morning newspaper

Finally, "electric spies," distributed in all the rooms behind the wall paper and the hangings and connected with sensitive microphones, make it possible for the master of the house, by pressing a button without leaving his bed, to know everything that is being done and said in the house.

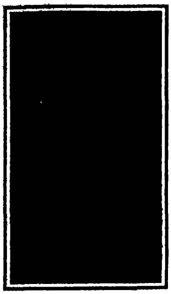
SOME PHOTOGRAPHIC DIVERSIONS.

BY GUSTAVE MICHAUD, COSTA RICA STATE COLLEGE.

Anachromatic lenses, such as the common spectacle lens, are sometimes used by photographers who aim at the production of artistic effects. The breadth of interpretation observed in pictures made with those defective lenses is a result of the suppression of small details. The impression left by the masses of light and shade is that which is felt before crayon work or oil painting, or before the landscape itself when we enjoy it, that is, when we are not paying particular attention to some minute part of it.



Fabric for the crayon effect

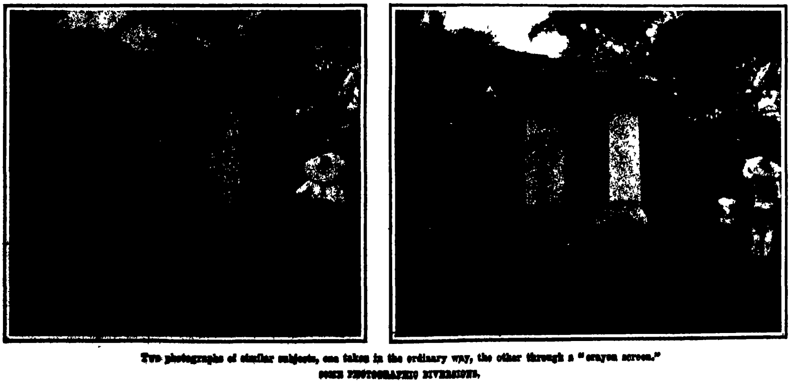
A landscape printed in the ordinary way.

Such artistic effects may be easily obtained with any objective, through the use of two implements, made once for all by the photographer himself, implements for which the names of "crayon screen" and "oil painting screen" would be appropriate

The crayon screen breaks the uniform photographic shades into numberless and irregular dots lines or spots, so that viewed through a magnifying glass they look very much like those produced by crayon drawn over rough paper The screen may be made by copying with the camera and without reduction, a layer of crayon uniformly laid over coarse drawing paper Better results are obtained by copying, with considerable reduction, some irregular design, made of spots, lines, and dots, on a printed fabric such as is found in every dry goods store Herewith is the reproduction in natural size of the fabric used for the making of the screen with which the crayon effect in the accompanying engraving was obtained If the screen is a film, it should be placed in the printing frame between negative and paper If it is a plate it is most conveniently used in the negative holder over the plate, and will then give after a rather long exposure a crayon effect negative Most holders will take and keep in place two plates of ordinary thickness

Same landscape as above made to represent the copy of an oil painting.

Photographs which look as if they were copies of artistic oil paintings may be made with any good negative and the help of the oil painting screen This is merely a negative made from any framed oil painting in which a piece of coarse cloth is substituted for the painting A print is made with this negative It is not toned or fixed and with penknife and rule, the cloth central part is cut out from the print This operation gives two paper masks one of the cloth and one of the frame Printing is made first with the negative of the landscape or portrait with the peripheral frame mask laid on the sensitized paper the holder being placed about normally to the rays of the full sunlight without ground glass but with a glass plate interposed between negative and paper The distance thus introduced destroys the small details, leaving only masses of light and shade The oil painting screen is then used in lieu of the negative It is placed in direct contact with



Two photographs of similar subjects, one taken in the ordinary way, the other through a "crayon screen."

SOME PHOTOGRAPHIC DIVERSIONS.

the paper and frame mask until the canvas effect is clearly seen on the print. Last, the central mask is substituted for the frame mask, and a third printing gives the frame. The oil painting effect is the result of the contrast between the small details of the canvas and the seemingly broad technique of the picture over it.

How Hydraulic Power is Exported.

The government of Denmark proposes to carry out with the aid of its engineers the following plan. Upon the southern shore of the Sund is found the old city of Helsingborg, not far from which the Lagu rushes down from an elevated plateau over a stretch of about 30 kilometers. A fall of 100 meters is situated not more than 2 kilometers from the mouth of the Lagu. It is at this point and for the purpose of using this important natural motive force, that it has been decided to establish a hydro-electric plant, transmitting its current to Helsingborg (first relay). The submarine cables traversing the Sund permit the distribution of the electric energy produced in Sweden over the territory of Denmark. The island of Seland, in which is found the Danish capital, will be the first to benefit by this installation, which will be very easily carried out, for between Helsingborg (Sweden) and Helsingör (Denmark) the arm of the sea is very narrow, not more than 5 kilometers wide, due to this circumstance the work necessary for the establishment of the submarine cables does not present any insurmountable difficulties.—La Nature.

Chinese Wild Silk.

M. Francis Marre, writing in Cosmos, gives some interesting particulars concerning the wild silk industry of China. A certain quantity of this silk, known under the name "water eel," is annually imported into France to be worked up in the factories of Lyons and Avignon, but the greater part of it finds its way to America, where it is made into a stuff called "radjah." Of late years, however, a considerable amount has been employed in the manufacture of balloons, a purpose for which it is peculiarly fitted by its strength and toughness.

The silk is obtained from a very common Chinese variety of the oak silkworm (*Antherea pernyi*). The larva feeds on the leaves of the *Cudrania triloba*, a dwarf oak which grows plentifully on the hills of Ho-Nan, Süchwan and Kweichou. A warm, moist climate prevails almost all the year round in this mountainous district.

The cocoons of the oak silkworm are treated quite differently from those of the domestic silkworm which is fed on mulberry leaves. They are hung in long festoons sheltered from the sun, generally in buffalo sheds, in order that they may be kept at a constant warm temperature. They remain thus until the Feast of Spring (at the end of January or the beginning of February), when they are removed and hung up in a large room, of which all the doors and windows are carefully stopped. A hole is made in the middle of the roof to allow the escape of the smoke from a stove which is placed in the middle of the room. The stove is kept steadily burning for twenty days, at the end of this period the moths emerge from the cocoons and pairing immediately begins, the males and females are then separated, the latter being placed in palm-leaf baskets, where they lay their eggs. This operation takes about five days. Each female lays on an average some sixty eggs, which are about ten times the size of a mulberry silkworm's egg. After another interval of from fifteen to twenty days, spent in the room which has been closed and heated as before, the worms are hatched and are then taken in the baskets to the places where their food grows. The baskets are set down under the dwarf oaks, the flexible young twigs of which are arranged by the natives so as to make it easy for the worms to climb up to the leaves.

The worm feeds for two months, and then begins to make its cocoon, an operation which takes a week. The cocoons are collected toward the close of May, i. e., from three and a half to four months after the removal from the warm chamber.

The silk is wound and spun in two ways. In the first, which is used to produce a coarse material, the thread is spun from twenty cocoons. Silk of this kind is manufactured almost entirely at Süchwan. In the second the thread is spun from eight cocoons, and silk of this kind, which is made for the most part at Kweichou, is in greater demand for export purposes.

A pound of cocoons produces, as a rule, 240 grammes of fine silk. The average price varies from year to year; in 1907 it was 15 francs the kilogramme, in 1908, 22.6 francs.

◆

Denatured alcohol costs more than gasoline and the quantity of denatured alcohol consumed by an alcohol engine as ordinarily constructed and operated is in general relatively greater than the quantity of gasoline consumed by a gasoline engine of the same type. It seems reasonable to expect a greater general improvement in alcohol engines than in gasoline engines.

Correspondence.

WHY WATCH SPRINGS BREAK.

To the Editor of the SCIENTIFIC AMERICAN:

I have read with considerable interest the discussion in the columns of the SCIENTIFIC AMERICAN relating to the breaking of main springs in watches. While the writer has had no direct experience along this line, the opinions given, while varying in detail and embodying many outside influences, seem to me to point to a common source, viz., the quality of material used in making the springs.

The opinion is constantly gaining ground among steel makers and steel users that the alloys and metallic compounds of iron are vastly more sensitive than those of any other metal, and that the composition and treatment of these substances constitute the foundation for their subsequent success or failure. The use to which the steel is to be applied should be known before the steel is made, and its composition as well as the process of its manufacture should be such as to produce the desired results. From practical results already attained, the writer is of the opinion that if these springs were made of a high-class crucible vanadium steel, and then subjected to a proper treatment, the trouble from breakage would be reduced to a minimum.

It would require too much of your valuable space to give reasons for this opinion, but I believe that a practical test of the material would lead to valuable results.

ELWOOD HAYNES.

Kokomo, Ind.

HOW DOES SAP RUN IN PINE TREES?

To the Editor of the SCIENTIFIC AMERICAN:

In about ninety per cent of all pine trees in this section, the fiber of the sap wood runs in a spiral around the tree contrary to the motion of the hands of a clock, i. e., from left to right in ascending the tree. This fact is easily observable in trees that have died, and from which the bark has fallen. Cyclones in the northern hemisphere revolve contrary to clock hand motion. Probably the cause is the same in both cases, liquid sap moving like cyclones. It would therefore be interesting to learn whether this fact in regard to pines is universal throughout the northern hemisphere, and in order to determine the fact of identity of cause with the cause of similar direction of revolution of cyclones it would merely be necessary to establish the fact that the fiber of pines in the southern hemisphere ascends in spirals that accord in direction with the motions of clock hands. Cyclones in the southern hemisphere, as is well known, revolve in the opposite direction from that of cyclones in the northern hemisphere.

Can some of your readers investigate along these lines, and report results? Does a top spinning in a vacuum weigh less than when it is not spinning? In other words, does the rotation of an object lessen its weight?

SAFEGUARDING MINES.

To the Editor of the SCIENTIFIC AMERICAN:

The recent mine horror in Cherry, Ill., being a sickening repetition of this sample of man's cruel neglect or indifference, emboldens the writer to trouble you with an indication, perhaps, of his ignorance merely, but which seems to him an idea that must have some value. He is not a trained mechanic, but living in a mining district and reading of the many coal mine accidents he has not been able to forego all speculation on the subject.

It would seem that the energy of the entire body of mining engineers has been given to the problems of preventing mine explosions and other accidents which damage mines and incidentally cost miners their lives. I do not recall any efforts of theirs to devise means to safeguard the lives of the miners who are entrapped every time an accident happens. A year or two ago some miners were imprisoned in a mine, and were saved by accidentally finding an old gas or water pipe, through which they communicated with their friends and through which their friends lowered food and drink to them. This fortunate rescue has suggested that for a comparatively small cost a mine room here and there (so situated with respect to size and number and location of them as would ordinarily give refuge to all workers who were not killed outright by the accident) could be so equipped as to give refuge to as many as might be necessary, and harbor them until the mine passages could be opened. Why could not such rooms be provided with two-inch pipes, such as the ordinary bored well has, or the smaller hole of the diamond drill if the depth or quality of the rock made it necessary? Through these tubes air could be forced down and the foul air forced out, and food and drink passed down to the prisoners. Such rooms could be supplied with fire-proof and air-tight doors, and each door could have a wicket through which a belated and choking straggler could be quickly admitted. If such a plan would work, surely the cost would be nothing comparatively, even to having a pair of two-inch pipes going down to each room, and then a strong pumping engine, by means of which large volumes of air could be constantly forced down. It will be objected that an explosion would destroy such rooms, to which the answer should be, it seems to the writer, "Leave the walls thick enough to withstand the worst of the ordinary explosions."

Surely, if such an idea or device would work, as it seems to the writer it must, the two or three hundred dollars that the equipment of each room might cost would seem a small expense to the mine owner if he had imagination enough to place himself in the place of the owner of the mine at Cherry. What would the owner of the Cherry mine give, if it were in his power, to instantly create enough such rooms as would give refuge to the three hundred men below, and be able to tell that frantic rabble of wives and mothers that owing to his foresight, humanity, and money, their men were safely cared for below, and would be fed, and they could communicate with them until the rescuers could release them? Under such conditions there would be no need to sacrifice the lives of those brave fellows who deliberately gave their lives by reason of their very eagerness to help their fellows.

Birmingham, Ala. GEORGE L. BROWN.

AN EARLY MARINE ENGINE.

To the Editor of the SCIENTIFIC AMERICAN:

The following from an old New York American may be of interest, especially at this time of looking up ancient types of steamships.

"In the year 1819, while experimenting for the improvement of the steam engine, my attention was arrested by the great loss of heat under the circumstances in which steam is generally produced, and the idea of my present generator suggested itself to my mind at that time; and in March, 1825, made the first experiment in R. L. Cawdrey's carriage shop, Ithaca, N. Y.

"I used a blacksmith's bellows to supply the fire with air, and concluded that about eight times as much steam was generated as air forced into the fire.

"The engine (which was installed in a Liverpool packet) is called a 'double steam engine,' having two steam cylinders of thirty five inches diameter, six feet stroke, two blowing cylinders of just half the capacity, which are worked by the engine, and the air is conducted into a boiler whose outer cylindrical case is four feet in diameter and twelve feet high, the furnace, or inner case, is three and a half feet in diameter and nine feet high. The fuel is introduced into it down the chimney, and it is so constructed that not one particle of heat can escape, but must absolutely pass into the water, together with all the gases generated by combustion, and become as strong an agent as the steam itself, passing through the steam cylinders with it."

The inventor, P. Bennet, of Ithaca, seems to have had a great deal of trouble with tar in his cylinder, as we would expect, but claimed to have overcome this difficulty.

WALTER C. BILSLUB.

Holbrook, Mass.

The Current Supplement.

The current SUPPLEMENT, No. 1770, may be regarded as a North Pole number, for it contains two articles on the Pole. One of them, by Washington Platt, gives a very complete history of Polar exploration, and shows what terrible hardships have been endured in the past in a quest which has no other reward than that of glory. Prof. Messerschmitt, on the other hand, contributes a strictly scientific article on astronomical and geophysical conditions at the North Pole. Although scarcely ten years have elapsed since Marconi made his first really conclusive experiment, wireless telegraphy has already become an art. Some recent developments in this art are reviewed by H. Marchand. W. B. Huff contributes an excellent article on demonstrations with the musical arc. "On Board the 'Parseval'" is the title of an article by Robert Saudek, in which he describes interestingly a trip in the famous German military dirigible. "Engine Power from Solar Heat" is the suggestive title of an article which will be read with much interest. A hop-picking machine which will have a marked effect on the hop industry is described and illustrated. In view of the return of Halley's comet, which has now been found by the telescope, some account of the great astronomer with whose name the comet is associated may prove of interest to the general reader. J. E. Gore contributes such an article. The continuation of the article on machines that make cordage, begun in the last SUPPLEMENT, is published. A. E. Shipley tells how zoology is being organized.

◆

Dr. Torp, rector of the University of Copenhagen, has selected Prof. Elis Strömgren, Director of the Astronomical Observatory, as head of the commission to examine Dr. Frederick A. Cook's records. These are expected at Copenhagen about December [illegible].

A NOVEL AERIAL RAILWAY.

A German engineer named Leps has conceived a novel and marvelously impracticable mode of transit, a sort of cross between the airship and the electric railway, in which a balloon supports the weight of passenger cars, which run on aerial cables and are propelled by electricity. According to Umschau, whence we derive our information, the balloon is a horizontal cylinder with conical ends of the rigid Zeppelin type of construction. It is about 300 feet long and 33 feet in diameter On each side, at the level of the axis, are pairs of small horizontal wheels which move between guiding cables supported by tall latticed steel towers. The function of these wheels and cables is to counteract the force of the wind A wheel on the windward side is pressed against the inner cable, and a wheel or roller on the leeward side is pressed against the outer cable, and thus the stress is equally divided between the windward and leeward towers, and also between the two sides of the balloon.

Beneath the balloon, and attached to it, are the cars, each of which accommodates 60 persons. The cars and connecting passages are made of steel, wood, and canvas, and provided with windows. There is a small forward compartment for the motor and the motorman. The larger compartment is furnished with revolving chairs and folding tables, for the use of passengers. Even toilet rooms are provided. The cars are heated and lighted by electricity, and are propelled by electric motors capable of developing a speed of about 125 miles per hour The motor shaft is extended outward, and each end carries a driving wheel which runs on a propulsion cable. Below this directly-connected wheel and the cable is another driving wheel mounted on a movable axis, so that it can be brought to bear on the cable from beneath. Thus the cable is pressed tightly between the concave rims of the two wheels, producing ample friction for traction, and the car is propelled as on an ordinary electric railway The propulsion cables, which are guide cables as well, are supported by latticed towers, which are shorter and lighter than the main towers, with which they are connected by trusses. An electric cable, suspended between the propulsion cables but at a lower level, furnishes current to the motors by means of contact wheels beneath the cars. The brakes are applied, not to the wheels, but to the propulsion cables.

At present this novel railway exists only on paper In order to test the practicability of the scheme it is proposed to construct a short experimental line from Marburg to the summit of a neighboring hill, the Frauenberg, 1,250 feet higher than the Marburg terminus. The promoters calculate that the operating expenses of a railway of this kind would be about one-fortieth those of an ordinary railway, and that the diminution in the cost of right-of-way would reduce the initial outlay to about $30,000 per mile. According to the estimates of the company, a line from Berlin to Hamburg could be constructed for less than $4,000,000, and the English Channel could be crossed at a cost of $5,000,000, while the 6,000-mile journey from Berlin to Vladivostock, which now occupies seventeen days, *via* the Siberian railway, could be accomplished in three days by the Leps aerial railway We would venture to point out that the limited number of passengers which an airship car could carry would mean a prohibitive fare. Count von Zeppelin, we believe, intends to charge $125 for a trip from Switzerland to Hamburg on one of his aeronautic "Lusitanias." Although there may be curious applicants in plenty for airship reservations, it is not likely that railways will suffer from Count Zeppelin's competition. There are engineering as well as financial objections to Leps's scheme. Zeppelin has found it difficult to anchor his airships in high winds. It is probable that storms will play havoc with an enormous gas bag held in place merely by rollers. A railway or foot bridge must be provided with more or less wind bracing if it is of any length, and it would seem that similar provision ought to be made for an airship train. The problem is hardly likely to engage serious attention, for it is not likely that this fanciful road will ever be constructed.

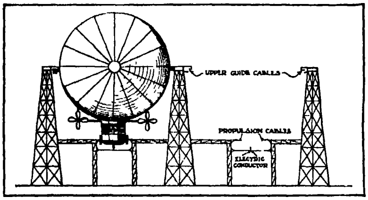

DIAGRAM OF LEPS AIRSHIP RAILWAY

* * *

In some metallurgical and chemical operations steam is admitted to large vats or tanks for the purpose of agitating and, in some cases, heating their contents. In special cases, the consumption of steam for this purpose is enormous. It is often possible to obtain better results by mixing air with the steam This may be accomplished by using an ordinary injector To insure the proper working of the device, the steam is first turned on, then the valve of the injector gradually opened, until the desired amount of air is obtained. By the use of this device, better agitation is secured, the contents of the tank or vat suffer less dilution, and there is a large saving in the amount of steam used.

Destruction of Wood Borers.

BY A. A. HOOPER.

In our waters there are two genera of mollusks, viz., Xylotrya and Teredo, and three of crustaceans, viz., Limnoria, Chelura, and Sphæroma, that attack and seriously damage structures of wood in salt water The Xylotrya and Teredo are very similar in structure and action The former are by far the more numerous, and what are commonly called Teredo are, in the large majority of cases, Xylotrya, and all references to the Xylotrya will be understood to refer to both genera.

When first coming to life the Xylotrya is very minute, being the thickness of a hair and about one-twentieth of an inch long. When very young it attacks the wood in countless thousands, and immediately begins to bore

In structure it is comparatively simple. Its body consists mainly of a tube beginning at the posterior end of the body, running to the head, and then returning to the posterior end. At the head end is a sucker-like foot or tongue inclosed in two shell valves which are provided with fine, hard, tooth-like protuberances It is with these valves that the boring is made. Through the longer end of the tube water is taken in, passed through the body, through the return tube, and is ejected through the shorter end with the wood borings and the excreta. It does not appear that the Xylotrya gathers any sustenance from the wood, its food consisting only of the infusoria in the water

Of the crustacean borers the Limnoria, or "wood louse," is the only one of great importance It is about the size of a grain of rice, and tunnels into the wood for both food and shelter The little galleries excavated are about one-half inch long and extend inward radially, side by side, in countless numbers, so that the wood partitions between them, which are very thin, are soon destroyed by wave action, thus exposing a fresh wood surface to attack.

A new method of destroying these borers has been found The piles to be treated are inclosed by a canvas apron supported by floats, and kept in an upright position in the water by weights at the lower end. The inclosed space is ordinarily not more than 40 x 80 feet square. The water in the inclosure underneath is decomposed by means of an electric current, and chlorine, with small quantities of bromine and iodine, are formed, rising through the water around the piles By a mechanical contrivance the apron and electrical terminals can be lowered to the mud level and gradually raised, the gases being constantly generated in the inclosure. As previously seen, the Xylotrya draws in water through one end of the tube always exposed, which passes through the entire body It has been proven that a mixture of one part of chlorine to one-half million parts of water is sufficient to destroy life in marine animals, so a very small quantity passing through this breathing tube causes death. As the Limnoria obtains a part of its food from the water, the same result is obtained with this type of borer It is true that one application of this method simply kills the borers existing in the pile and surrounding waters, and does not prevent further ravages from others, but the process is so cheap that it can be applied as often as necessary, say every two or three months, thus insuring long life to an unprotected pile.

A public demonstration of this method of destroying wood borers was recently made in the waters of Elliott Bay, the inventors using for the purpose of generating the chlorine gas a current of 100 amperes at about 12 volts.

After the treatment the pile was left in the bay for twenty four hours, in order that should there be any power of revival it might manifest itself, then it was cut open, and all Xylotrya were found to be dead The result was accomplished principally by the corrosive action of the chlorine upon the exposed parts of the Xylotrya, that is, the so-called "tail" which in reality constitutes both their feeding and breathing organs. It appeared that all exposed tails in the pile thus treated turned white, while when the animal is alive, they are a dark gray As the chlorine penetrated the borer it coagulated the albumen which constitutes part of the body and which shows itself in white spots. The original appearance of the Xylotrya when alive is almost transparent and glassy

The Quebracho Tree of South America.

The quebracho is a tree of South America (Argentine Republic), where it forms entire forests, but nevertheless has been, until now, almost completely unknown. Its use is now beginning to spread among tanneries, and for two reasons First, its high content of tannin, which amounts to 18 to 20 per 100 pounds weight of wood and bark, second, the discovery of chemical methods of treating the extracts, which facilitate the employment thereof It was a German tanner of Buenos Ayres who was the first to find that extracts of quebracho wood were able to tan hides, but the first sample of the wood was carried into Europe by way of Havre in April, 1875 by Dubosc who undertook the industrial manufacture of the extract. The employment of the extract developed difficulties consequent upon the peculiar property of the tannin When one extracts the tannin from the bark by boiling water, the *solution deposits on cooling* the insoluble tannin, while there remain in solution soluble tannins and the glucosides, or non tannins These three components operate during the tanning the soluble tannins combining with the fundamental substance of the skin, the non-tannin fermenting and giving the acids, which are necessary for "plumping the hides, and which facilitate the absorption of the tannin, the insoluble tannins finally penetrate uniformly into the pores and render the hide impermeable The quebracho is composed of 20 parts of soluble tannins in 100 parts, and only 2 5 of non tannins per 100 while it does not contain any glucosides, it is therefore not able to furnish enough acid by fermentation But if one adds thereto acid liquors resulting from other extracts, there is produced a precipitation of soluble tannin, which renders the tanning process very difficult.

Attempts have been made from the first to eliminate the insoluble tannins by addition of lead acetate, alum, albumen etc and to thus obtain a clarified and decolorized extract, but these attempts have not solved the problem. After that endeavors were made to render the insoluble tannins soluble two Italian chemists, Leptit and Tagliani found that by a treatment with alkaline bisulphites, the non soluble compounds were able to remain in solution and also in the acid liquors This process patented in all countries, has made feasible the universal employment of quebracho In the United States there was employed in 1901 not more than 5,000 tons of extracts, in 1907 six years after the discovery of the bisulphite process, 50,000 tons were consumed, in 1909 70,000 tons The extraction is effected *in situ*, on the Parana River is found a plant producing 50,000 tons per year —La Nature.

* * *

Wireless Telegraphy Between London and South Africa.

There are being carried out at this time trials looking toward the establishment of direct telegraphic communication by wireless between South Africa and England, this is being done at Durban in Natal. In spite of the immense distance, it is hoped that a satisfactory result will be obtained particularly since it is known that the propagation of Hertzian waves occurs with much greater facility along the meridians of longitude than it does over the parallels of latitude In undertaking the operation of wireless telegraphy between America and Europe a task was assailed which was really more difficult Fortunately in this latter case, the fogs of high latitudes furnished facilities which may perhaps not be found in the South African line.

Since high towers are very expensive to erect, it is proposed to supplant them at Durban by kites, which will carry to a height of 300 meters the extremities of the antennæ and it has already been estimated that the cost for transmitting messages may be successfully placed at 1 25 francs per word.—Cosmos.

* * *

Water Varnishes—Solutions of resin in alkalies and water have been suggested as cheap varnishes but owing to their lack of durability they are used only for common painting Their preparation is very simple dissolve the alkali (soda or potash) in the quantity of water decided on heat it to boiling add the resin gradually in small quantities stirring constantly and clear by standing Floor varnish with shellac 80 parts water, 3 parts crystallized soda 5 parts shellac Floor varnish with shellac and color 20 parts water 2 parts crystallized soda 4 parts shellac, 4 parts washed ocher The varnish is prepared as at first described, the ocher is added after cooling and thoroughly shaken up, and the whole ground in a paint-grinding machine.

HOW TO OBSERVE AND RECORD THE WEATHER.

BY THALSON BLAKE, C.E.

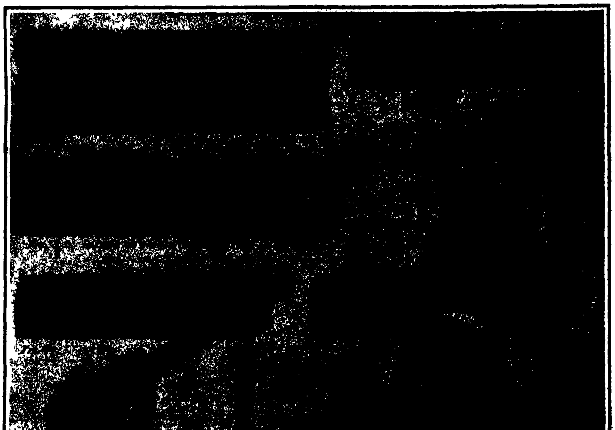
The weather is always with us Upon its condition depends our physical comfort, our material welfare, our food supply, our outdoor amusements our sports, and to a certain extent the prosecution of our business enterprises Because men are so intimately so profoundly affected by environment, the study of climate is receiving more and more attention from progressive governments

Each day wears its appropriate dress summer or winter and the observation of this daily individuality of the weather constitutes a major part of the duties of weather observers The United States Weather Bureau forecasts the weather, issues storm warnings, displays frost cold wave and flood signals, receives, tabulates, and distributes meteorological information for the benefit and safeguarding of agriculture commerce, and navigation About two hundred regular observing stations are maintained in the United States and the West Indies, each in charge of a trained observer, who telegraphs to Washington the weather conditions from his local office twice a day—8 A. M and 8 P M, seventy-fifth meridian time

On these observations are forecast the weather conditions for the ensuing thirty six to forty eight hours All of these stations have mercurial barometers, thermometers, wind vanes, rain and snow gages, and anemometers Many of them have in addition sunshine recorders, barographs, thermographs, that register, automatically and continuously the changes of the weather The governments of Mexico, Canada, England, Germany, France, Portugal and some others, more or less effectively, maintain similar services so that, by exchange of information the weather conditions that obtain over North America North Atlantic Ocean, and West Europe are very thoroughly observed, and forecasts made with dispatch and accuracy

The art of predicting the most probable condition of the weather for the ensuing twenty four to forty eight hours depends on the observations over a considerable area, and on the experienced judgment of the forecasters in predicting conditions likely to follow those at the time of taking the observations

There seems to be much mystery attached by the general public to the observation and recording of the weather This supposition is erroneous. The weather itself is seldom complex. At a given hour on any day, it is hot or cold, the sun shines or the sky is overcast, it rains or snows, or there is no precipitation, the air is calm or breezes blow, or there is a hurricane. The weather being reducible to such simple terms, it follows that a comprehensive record of observations need not be abstruse to be valuable. Nor is the observation of the weather by co-operative observers of the Weather Bureau difficult to learn or to take The great extent of the territory of which it is necessary to have reports, would render impossible any large corps of observers if they all had to be paid. Fortunately, hundreds of people are interested enough to volunteer their services to the government. This enables the Weather Bureau to multiply its observers at little more cost than that of supplying the instruments and the stationery, all of which are lent to responsible and experienced volunteers. The co-operative observers, as a whole, although serving without pecuniary compensation, display much interest and care in their work. Through its principal stations, the Federal government supplies the co-operative observers with thermometers, a shelter in which to house them, and a rain gage. Some may have a larger equipment, but these comprise the customary number.



HOW WEATHER DATA ARE COLLECTED FOR THE WEATHER BUREAU BY AMATEUR OBSERVERS.

It is required of co-operative observers that they read the thermometers once a day, at 7 P. M. The temperature is read on thermometers exposed to free air Two thermometers are necessary to obtain the highest and lowest temperature, named, respectively, the maximum and the minimum thermometers. The minimum thermometer registers the lowest temperature for the past twenty four hours. It is filled with alcohol, and its registering of the lowest temperature is accomplished by means of a double-headed, pin-like object, called an index, that slides freely in the alcohol within the glass tube. Solely because the index remains in the alcohol, it is enabled to go down and register the lowest temperature of the period since it was last "set." (Fig. 1)

For instance, if, during the night, the temperature falls from 85 to 50 degrees, the alcohol column descends, of course, toward the bulb. Then the end, or top surface, meets the head of the index and takes the index down with it. While the index will not suffer the alcohol to pass on down, and leave it in the vacuum above, it will allow the alcohol to flow above it, meanwhile remaining at rest at the lowest point reached by the top of the column of alcohol. It is obvious that because the index will not permit the surface of the alcohol column to flow past it on the way to the bulb, but will lie still when the column of alcohol flows upward with the increase of warmth, the lowest temperature is registered. The maximum thermometer is designed to register the highest temperature of the preceding twenty-four hours. It is filled with mercury, which, owing to a stricture in the tube near the bulb (Fig. 2), can flow freely from the bulb as the temperature rises, but when the temperature falls, it cannot easily flow back. Thus imprisoned above the stricture, it registers whatever degree was the highest attained by the temperature for twenty-four hours.

The words "top" and "bottom" are used advisedly, as the minimum and maximum thermometers are

(Continued on page [illegible].)

TESTING THE MAN-ENGINE

BY JOHN ELFRETH WATKINS.

Of the many man-engine testing plants which have been instituted within recent years the most interesting are those which are now studying the self-directing function of the human machine In these workshops man is continually making surprising discoveries about himself

Perhaps the most engrossing item in their equipment is a gage for use in determining the man-engine's speed in starting stopping or directing its course after receiving a signal It is a clock which records thousandths of a second and an electric current can start and stop it within an imperceptible interval Several complicated instruments can be connected with it in such a manner that upon the instant a sound is made a light is flashed or a color a letter or a word is exposed the electrical impulse giving such a signal will start the recording hand

The subject with a finger pressing a telegraph key is told that as soon as he hears sees or feels the signal he must release his finger from the key The signal itself automatically closes the current and starts the clock while the lifting of the finger from the key breaks the current and stops the clock The number of thousandths of a second scored by the clock meanwhile measures the time required by the mind in perceiving understanding and obeying the signal

Thus this man-engine gage will measure the time which you require to recognize or name a letter color or object to read a word or sentence to add subtract multiply or divide to remember your own name your address the meaning of any word in any language Comparative tests thus far indicate that the average mind obeys a sound signal in 125 thousandths and a light signal in 160 thousandths of a second and that the ear therefore is quicker than the eye also that the eye requires about the same time to read a word of five or six letters as to read a single letter that a person remembers his own name more quickly than that of his best friend—even that of his wife that he recollects the country in which his own city is located more promptly than that in which Paris is for instance According to Prof Lightner Witmer of the University of Pennsylvania men hear see or feel signals more quickly than do women and Indians appear to be quicker in this respect than are whites

Of all the man-engine's working levers the arm is the most industrious The quickness of its movements

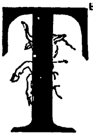
TESTING THE MAN-ENGINE.

THE HEAVENS IN DECEMBER.

BY HENRY NORRIS RUSSELL, PH.D.



THE prediction of the return of a periodic comet involves a number of difficulties which are not met with in similar calculations concerning the planets. Comets, especially those of long period, move in very elongated ellipses, and can be observed only when relatively near the sun, since at great distances they are too faint to be detected. We have therefore to determine the form and dimensions of the orbit from an "observed arc" which may be only one-tenth or one-twentieth of the whole

A very small error in the observed positions—which may easily occur, especially for a comet which has no sharply defined nucleus—may thus lead to a much greater uncertainty in the calculated dimensions of the orbit, and the resulting time of the next return.

In much the same way a small change in the direction or rate of the comet s motion, such as may be caused by the attraction of a planet near which it comes, may lead to considerable changes in its period, and in the other elements of its orbit. These changes, unlike the effect of observational error, may be accurately calculated, though only by very laborious processes.

When a comet has been observed at two or more returns the influence of observational errors is greatly diminished, and its future behavior, or its past history, can be determined with a high degree of accuracy

It is thus possible to utilize the ancient chronicles of astronomical events, which have been preserved in various parts of Europe and also in China and to see whether earlier relics of the body under investigation can be identified

It is of course insufficient to find the mere statement that a comet was seen in a certain year, for there are many cases on record when two comets were visible within that interval We need specific information from which the comet s apparent place in the heavens at a known date can be inferred If this agrees with our calculations, or, at least, does not depart from them more than is reasonable to attribute to the errors of naked-eye observations and rough descriptions, the identity of the comet is assured

This procedure has been adopted by Messrs Cowell and Crommelin of the Greenwich Observatory, whose work is noteworthy no less for its practical ingenuity, from the standpoint of the calculator, than for its signal success

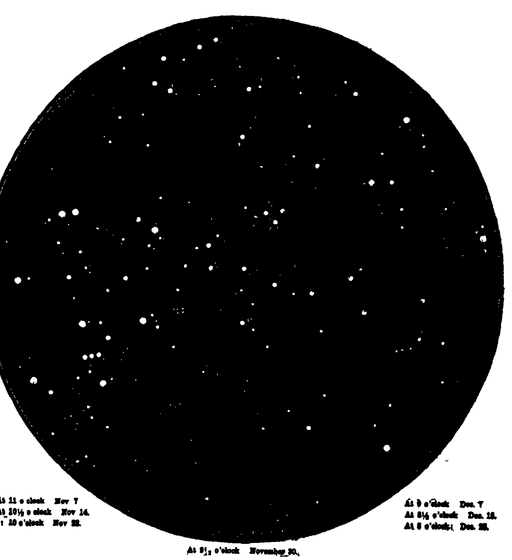
Working backward from the last return in 1835, they found returns in 1759, 1682, 1607, 1531, 1456, and 1378 already definitely established by the work of preceding astronomers Those of the sixteenth and seventeenth centuries were the basis of Halley's notable discovery of the periodicity of the comet, which causes it to bear his name The next previous return should have occurred on October 26th A. D 1301, only four days later than the date deduced by Hind from the Chinese observations of a comet in that year The difference is quite within the errors of such rough estimates of position It is noteworthy that the European observations (or at least the existing records) of the same comet are much less accurate than the Chinese—a curious reversal of the present state of things. Still working backward, the returns of the comet in the years 1222 1145 1066 (a famous comet which appeared just before the Norman Conquest of England) and 989 can be identified in the chronicles

At the preceding perihelion passage in 912 there are vague references to a comet or comets, in addition to a bright one which appeared some four months earlier than Halley's could have done but nothing sufficiently precise for identification. On the other hand, the return in 837 is well described, and that in 760 was recorded by the Chinese with sufficient detail to enable M. Laugier many years ago to show from the observations alone that the orbit of this comet, in its visible portion, was practically the same as that of Halley's comet.

The return of A. D. 684 was observed in China and Japan. In 607 at least two comets appeared, one of which was doubtless the object of our study The apparition in 530 is again definitely identified, and the Chinese observations of 451 are by themselves conclusive as to the comet's identity.

Even here the end is not reached. The returns of A. D 373, 295, 218, 141, and 66, all appear to have been observed and also those in B. C. 12 and B. C. 87 A comet observed in China in 240 B. C was probably a still earlier return Beyond this there are no sufficiently definite observations, though a record of a comet seen in B. C. 467 may perhaps refer to a still earlier apparition

This is an impressive record, which may well give rise to reflection—on the indefatigable energy of the computers, and not less on the remarkable care of the ancient star-gazers and of the scribes who preserved their records. But from the standpoint of general interest, it is most of all noteworthy that the comet has been a conspicuous naked-eye object at at least twenty four out of its last twenty-six returns, and probably at the other two, where the records are incomplete. We have therefore very good reason to anticipate a fine sight next May when the comet will be for a few days unusually near us.



At 11 o'clock Nov 7
At 10½ o'clock Nov 14.
At 10 o'clock Nov 22.

At 9 o'clock Dec. 7
At 8½ o'clock Dec. 15.
At 8 o'clock Dec. 23.

At 9½ o'clock November 30.

NIGHT SKY: NOVEMBER AND DECEMBER

At the present apparition, the twenty-fifth which has been certainly observed, the comet is still too faint to be seen without a large telescope, and will remain so until early in the new year In spite of its faintness, its spectrum has been photographed at the Lick Observatory, showing no trace of bright lines or bands, but only a faint continuous spectrum, such as reflected sunlight would give with the instrument employed

The awakening of the comet's activity as it approaches the sun had apparently not yet begun. Its progress will be of great interest.

THE HEAVENS.

There is no time in the year when so many of the brightest stars can be seen at once as at present. Looking first to the westward, we find Altair in the constellation of the Eagle, just setting at the hour assigned on our map, but clearly visible a little earlier Almost due northwest, and a little higher, is Vega, above which is the less brilliant but equally white star Deneb, in Cygnus. The lonely star low down in the southwest is Fomalhaut.

Above this the southern and western sky boasts no very bright stars, but the planets Mars and Saturn are there, close together, in Pisces.

The finest group of all is in the southeast. Low down, and twinkling violently in the winter air, is the splendid Sirius. Above him is Orion which boasts two stars of the first magnitude—Rigel on the right and the ruddy Betelgeux on the left. Due east, and low down, is the lesser Dog-star Procyon. Above on the left are the twin stars Castor and Pollux, and higher still is the brilliant Capella. Across the Milky Way from the last is Aldebaran, the brightest of the stars of Taurus.

This fine constellation, which is shown in our initial, is, like Pegasus, supposed to represent only the head and fore-legs of the Bull. The stars β and ζ on the edge of the Milky Way, mark the tips of his horns. Aldebaran is one of his eyes, and the little V-shaped group of the Hyades, of which it forms a part, marks his face, while the Pleiades are in his neck. Like all the animal-figures in the zodiac, the constellation is of very great antiquity

Of the constellations not already mentioned we may note the vast and faint areas of Eridanus and Cetus in the south, and the familiar forms of the two Bears and the Dragon beneath the Pole, of Perseus, Cassiopeia, and Andromeda high above us, and of Pegasus to the westward.

THE PLANETS.

Mercury is morning star until the 3rd, and later evening star, but is not favorably placed, and can be seen only at the end of the month, when he sets about 5 45 P. M. far to the south of west.

Venus is also evening star, and is very conspicuous. She is at the greatest elongation (apparent distance) from the sun on the 2nd but is then far south and becomes still more prominent as she comes northward. By the end of the month she remains in sight until after 8 P M and is very bright.

Mars is in Pisces, and comes to the meridian about 7 P M in the middle of the month. He is moving eastward among the stars, toward Saturn, whom he overtakes on the last day of the year, passing about three degrees north of him. By this time he is 90 million miles distant, and only one-eighth as bright as he was in September

Jupiter is morning star in Virgo, rising about 1 A. M. in the middle of the month.

Saturn is in Pisces, near Mars, from whom he can be distinguished by the yellow color of his light. Uranus is in Sagittarius and unobservable. Neptune is in Gemini, approaching opposition, and is visible (with sufficient telescopic power) most of the night.

THE MOON.

The moon is in her last quarter at 11 A. M. on the 4th, new at 3 P. M. on the 12th, in her first quarter at 9 P. M. on the 19th, and full at 4 P. M. on the 26th. She is nearest us on the 23rd, and farthest away on the 7th. In her circuit of the sky she passes Jupiter on the 6th, Mercury on the 13th, Uranus on the 14th, Venus on the 16th, Mars on the 20th, Saturn on the 21st, and Neptune on the 27th.

At the present new moon there is a partial eclipse of the sun, which, since it is visible only in New Zealand and the Antarctic regions, is of little account.

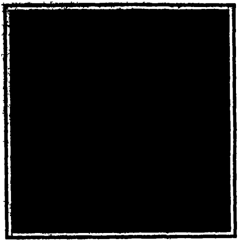
CURIOSITIES IN SCIENCE AND INVENTION.

PEDALING ON WATER.

Every once in a while an inventor comes forth with some new contrivance for traveling over water, which though of no practical utility is interesting because of its novelty or oddity. Pictured herewith is a very queer craft comprised of three floats which support a bicycle frame. The navigator sits on the bicycle seat, operating the pedals in the usual way, and the latter are geared to a screw propeller, which drives the craft forward. The front float serves as a rudder As progress is rather slow, a small sail is provided, which is attached to the forward float of the craft.



A CURIOUS SAIL AND PEDAL PROPELLED CRAFT.

◆

THE ICE DRAG OF THE WELLMAN EXPEDITION

One of the curious contrivances gotten up for the Wellman airship expedition to the North Pole was a drag that would retard backward drift when the airship was encountering head winds too strong to permit of anchoring It consisted of a long leather tube, armed with steel spurs adapted to dig into the ice, as it trailed over the surface The tube also served as a reservoir for food It was ingeniously figured out that as the balloon gradually lost its lifting power because of the leakage of gas, the drag would also become lighter because of the consumption of food, and thus its dragging effect would always be proportional to the weight of the airship.

AN ICE DRAG FOR AIRSHIPS.

◆

AN EARLY TYPE OF SUBMARINE BOAT

Whenever a prominent invention is reduced to practice, the inventor finds his claim to originality called in question by the work of some obscure inventor living generations before. It does really seem as if there were nothing new under the sun. In the early part of the last century a friend of Herr Leeghwater, the celebrated Dutch engineer, spent all his fortune and ran deeply into debt by constructing a model of a submarine boat. Illustrations of this remarkable submarine are shown herewith. The boat was of porpoise shape and was designed to be driven by four men turning a fly wheel The latter operated fan like valves working in the orifices under each bow, thereby drawing in water, which afterward was forced out in jets by means of pistons also operated by the fly wheels. The boat was trimmed by means of weights moved along the tramway shown at each side The conning tower was telescopic so that when diving far below the surface, where the pressure of the water would be too heavy on the glass windows the tower could be collapsed. Unfortunately the name of this early inventor has been lost.

COIN-OPERATED DEVICE FOR REGISTERING LETTERS.

In one of the city post offices in Paris there is an apparatus which automatically registers letters, and issues a receipt for the sender of the letter The apparatus is arranged to receive the French nickel or 25-centime piece Advantage is taken of the fact that it is slightly magnetic, for in passing down the coin chute it is obliged to leap a gap and is prevented from dropping through by means of a magnet. A counterfeit of iron cannot pass the gap because it would be lifted up by the magnet, while non-magnetic coins would fall through The letter slot does not open until after the coin is placed in the machine, and the receipt is not issued until after the letter is placed in the machine The receipt, in the form of a ticket is dated and stamped by turning the crank at the side of the apparatus. The whole operation is performed in less than five seconds, and is calculated to do away with the long line of waiting applicants at the usual registering windows. The apparatus can also be placed in banks or stores, where there is no danger of its being stolen thus relieving the pressure at the regular post office

THE GREAT STONE GLOBE AT SWANAGE.

A peculiar monument is set up at Swanage Dorset County, England It consists of a globe 10 feet in diameter and weighing 40 tons. On it the continents and oceans are shown, the former in slight relief Carved in the globe are the meridians, parallels of latitude, ecliptic, and tropics. The axis of the globe is inclined to correspond with the inclination of the earth's axis with respect to the ecliptic, but unfortunately the inclination is not in the right direction Were the axis of the globe parallel with the axis of the earth, observers would be able to get a correct idea of day and night in different parts of the earth when the sun is shining on the stone globe. The monument is intended as a lesson in astronomy Engraved on tablets of stone about the globe are data concerning dimensions of the earth, etc

We have not heard the last of the "Mauretania's" great steaming powers and performances Toward the end of the year when the passenger season slackens down, the Mauretania will go into dry dock and be fitted with new propellers designed at Wallsend and specially intended to utilize the vessel's reserve of engine power which has not yet been called into full play The propellers are similar to those which have recently been fitted to the Lusitania ' and with such good results that the vessel immediately broke the record The Mauretania however soon responded, and went one better even with her old propellers. With the new ones when fitted it is naturally expected that she will do still better Indeed the builders and engineers of the Mauretania' anticipate making her a 26-knot ship at the least for her special advantages in design and engine power will be brought out to their full capacity —The Mariner

SPRAY HELMET FOR FIREMEN

Firemen frequently find it necessary to play the hose on their fellow firemen to protect them from the intense heat of the conflagration which they are fighting Borrowing from this idea an inventor has devised a helmet formed with a spray nozzle which is connected to a small hose line The water spouts out from the nozzle in all directions causing a miniature cascade around the body of the fireman enabling him to attack at close quarters fires that would be unendurable under ordinary conditions

FIREMAN PROTECTED BY A SPRAY HELMET.

INDOOR BED TENTS.

BY KATHERINE LOUISE SMITH.

Fresh air at night and plenty of it is the cry that is going up among those who are determined to subdue the "Great White Plague," and with these persons it has become more than a fad, a necessity Those who have resolved to abstain from kissing even their nearest and best, are now either seeking some practical method of sleeping out of doors, or planning some device whereby a good supply of fresh air may be obtained in warm bedrooms. Many persons are building screened porch bedrooms just outside of the sleeping rooms, where they can sleep in the patent sleeping bags that leave only the head exposed and that come with pockets for holding the hands. These persons dress and undress indoors, and jump into their twenty-dollar sleeping bag after adjusting a warm hood and muffler But though the muffler can be drawn over the head so that only the eyes are exposed, and though it is made of heavy wool and elastic there is in this outdoor sleeping bag danger of catching cold between the warm room and the outside bed

So these fresh-air enthusiasts are casting about for some method that shall keep the body warm, the head exposed to the fresh air, and the bed adjusted in such a way that undressing and passing to the bed can be conducted in a warm room To fill this need several devices have been invented, but they all fall under two heads—one where the person sleeps with his head out of the window, and the other where the bed is rolled to the open window, and a tent employed to drop over the sleeper's bed.

The cost of the ordinary window bed is moderate It can easily be made by any carpenter, as it is constructed of an ordinary hospital bed with the legs adjusted eighteen inches from the end These are just long enough to raise the bed so it can go over the sill The head of the bed at night is thrust through the window, the sleeper creeps into the bed with his head outside the window and draws an awning down over his head, which protects him from inclement weather and at the same time does not exclude the air A wide strip of felt is fastened to the lower sash of the window to keep the air out of the room In this way the sleeper has his head outdoors and his body under the bed clothes in a warm, heated room There are however two objections to this bed though it is so simple it can be made at home These are that in cases where it protrudes through a window above the first floor, there is often the uncomfortable sensation that one may fall, and the other is that the bed shows from the outside of the dwelling

For these reasons many persons are using the new fresh-air tents which are fastened inside the window While several varieties are made, they all involve similar principles of construction, and they have the merit of not being conspicuous. In using the window tent, the side of the bed near the top is placed next to the open window The tent, which is made of heavy canvas or awning cloth, comes down from the inside of the window over the side of the bed and over the pillow It reaches to the middle sash and can be adjusted by tightening a screw, and is capable of being moved from one window to another With the head once under the tent, one can actually breathe the fresh air from the window, while the rest of the body is in the bed covered by the bed clothes and in a warm room

These tents have become popular for they are large enough so that the face can be close to the window or on the pillow and three feet back. A little celluloid window in the side of the tent next to the room allows the user to look out and to converse with those

(Continued on page 423)

AN EMERGENCY OXYGEN USE FOR MINERS.

BY [illegible]

Clarence Hall, explosives expert for the government, has just announced the invention of a safety device which, had it been in use a few weeks ago, might have saved hundreds of lives at the mine of the St. Paul Coal Company at Cherry, Ill. The device is a simple appliance, which generates sufficient oxygen to sustain life for a half hour or so under any conditions of atmosphere. Had the miners who died in the recent disaster been supplied with this apparatus, the densest of smoke or an atmospheric condition entirely devoid of oxygen would not have killed them They would have been enabled to remain alive until the supply of oxygen was exhausted.

MINER'S EMERGENCY OXYGEN OUTFIT.

The newly invented oxygen generator guarantees a lease of life for a time ranging from a half an hour to an hour while a man is fighting his way to the open air or awaiting the coming of rescuers. The invention was made by Mr Hall while in the government service.

The manner in which the inventor hit upon the idea of supplying oxygen to the entombed miner was casual in the extreme Mr Hall was lighting the lamp of an automobile, when the thought occurred to him of generating oxygen as the gases of the lamp were generated, and supplying that oxygen to miners to breathe when the air of the mine had become so contaminated with poisonous gases and smoke as to spell immediate death. Accordingly he made a device which consists of a water chamber, and below it a compartment filled with sodium peroxide In an emergency, a stopcock is touched, and the water comes in contact with the chemical The oxygen is generated This is passed through the water, which cools it. Then it passes to the mouth and nose by means of a mask, such as is fitted to the face when gas is ordinarily administered by a dentist. Thus may oxygen be supplied that will keep a man going for half an hour while he fights his way out of a mine filled with gas or smoke

Mr Hall as a representative of the government studied many of the great disasters in mines that have occurred in recent years At Mononga, where more than three hundred men lost their lives in December, 1907, he found that the vast majority of the men had died by slow suffocation long after the explosion. Many of these had crawled for great distances on their hands and knees, for the miner knows that the best air is near the ground. Their trousers were worn through at the knees, and their blood marked their trails. Their fingers were worn through to the bone from crawling.

Of all men who die in mines, ninety per cent meet death through suffocation There are in the United States 700 000 men who work in coal mines. Many of these are daily subjected to the danger of suffocation Every year 4,000 of them go to their deaths in this way The ordinary safety devices are expensive. The men cannot have them always at hand, even if they could afford the expense.

The new device can be slipped into the coat pocket, and kept with the coat and lunch basket, always within reach.

Mr Hall is in charge of the explosives station in Pittsburg, recently described in the SCIENTIFIC AMERICAN SUPPLEMENT That station, it will be remembered, has a large chamber in which all sorts of poisonous gases may be confined and into which men are sent to demonstrate various appliances. Various kinds of oxygen helmets which will keep a man going for two hours were tried out here.

In this demonstration chamber Mr Hall burned excelsior in the chamber until the smoke was so thick that the eye could not see four inches through it. Then he donned his oxygen-producing device and went in He remained here quite comfortably for fifteen minutes. Then the smoke pained his eyes and drove him out. The device continued to generate oxygen, and other men entered the chamber with entire safety for more than half an hour

A New Chromatic Circle.

The principal purpose of a chromatic circle is to show the true complementary color corresponding to any given tint. Rosenstiehl has attempted to correct the old error of regarding red and green, yellow and violet, blue and orange, as pairs of complementary colors. These false notions were introduced by Robert Waring Darwin at the close of the eighteenth century. They have been perpetuated by the chromatic circle used in the Gobelins tapestry manufactory and popularized by a lithographic copy of that circle, made in 1861, which is the only document at the disposal of French artist-artisans.

Rosenstiehl's experiments show First, that the true complementaries of red and orange are not green and blue, but two tints near together in the green-blue region, second, that the complementary of yellow is not violet, but blue, third, that violet is the true complementary of green. The differences between the true complementaries and the false complementaries of Darwin are sufficiently great to warrant the construction of a new chromatic circle. Rosenstiehl's circle comprises twenty four colors, which form twelve exactly complementary pairs. A neutral gray is produced by the rotation of a disk, half of which is covered with each color of any pair of complementaries, and all the grays thus obtained are very nearly identical This condition, very difficult to realise in practice, implies not only equal intensities of the two colors of a pair, but sensibly equal intensities of all the colors. The result is in accordance with the Young-Helmholtz theory of the three fundamental color sensations.

◆

The first bituminous coal mined in the United States, states the United States Geological Survey, was taken from what is usually termed the Richmond Basin, a small area in the southeastern portion of Virginia, near the city of Richmond. This basin is situated on the eastern margin of the Piedmont Plateau, 13 miles above tide water, on James River It lies in Goochland, Henrico, Powhatan, and Chesterfield counties. The coal beds are much distorted, and the coal is of rather low grade, when compared with that from other districts with which it has to come into competition The occurrence of coal was known in the Richmond Basin as early as 1700, and in 1789 shipments were made to some of the Northern States. In 1822 the production amounted to 48,215 gross tons. At present what little coal is produced in this field is for local consumption only.

INDOOR BED TENTS.

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

SEPARABLE FASTENER FOR BOOTS AND SHOES.—J. [illegible], Salt Lake City, Utah. One of the purposes of this invention is to provide a simple, durable and effective means for drawing together the upper of a boot or shoe from the top of the vamp, and holding the upper closed over the front of the foot from the instep to the ankle.

COMB.—W Jacobs, New Orleans, La This invention is an improvement in combs, being adapted for embodiment in ladies' dressing and back combs as well as in pocket combs for use by men. The article presents an attractive appearance and combines with a comb, a mirror conveniently arranged for use as desired

BUCKLE.—A, Birkenbucht, New York, N Y The buckle is more especially designed for use on men's trousers belts, and arranged with a particularly shaped hook on the tongue, for engagement with the fastening device used for closing the flies of the trousers, to hold the belt against upward movement on the trousers.

Electrical Devices.

ELECTRIC PROCESS FOR MAKING PICTURES.—B D Avis, Jr, Wallace, W Va. In the present patent the invention has reference to picture making, and the more particular purpose is the provision of a method and means for developing by electrolytic action a sensitive plate or analogous member which has been previously affected by the action of light.

VISUAL-SIGNAL APPARATUS.—R Einbigler, New York, N Y The object here is to provide an apparatus for use in stock exchanges, factories, and mercantile establishments, and arranged for summoning a person to a meeting place by displaying the person's name number or other indicating character, and also a station or place to which the person is directed for meeting the caller It relates to apparatus such as shown and described in Letters Patent of the U S, formerly granted to Mr Einbigler

Of Interest to Farmers.

COMBINED FERTILIZER DISTRIBUTER AND PLANTER.—F W Decker, Brunswick, Ga This device has the advantage over the ordinary type of planter in that the work in carrying out the operation is materially reduced To this end a two wheeled machine is provided which is capable of delivering the fertilizer, drilling the ground preparatory to planting the seed, depositing the seed in the drill, and covering the seed after planting

CORN PLANTER.—C W Lanham, Hustonville, Ky, This invention includes a special construction of main and auxiliary frames, the auxiliary frame being arranged at the front and pivotally supported. It carries the seed boxes and dropping mechanism. The various novel details characterize the adjusting and controlling means for the auxiliary frame and the parts carried thereby

Of General Interest.

PAPER DECORATION —A Simonson, New York, N Y The invention pertains to decorations or festoons, and the intention is to provide a collapsible paper festoon formed of a plurality of layers of tissue paper or similar material, so cut and pasted as to be readily expanded for use as a decoration or garland.

INTERLOCKING BUILDING BLOCK.—B Benas, New York N Y The purpose of the inventor is to provide a new and improved interlocking building-block, for forming walls, partitions, floors and like structures, and arranged to interlock endwise and sidewise with adjacent blocks to form an exceedingly strong and durable structure

SUBMARINE MINE.—A. P. Broomell York, Pa. In the present patent the invention is an improvement in submarine mines or torpedoes and it has for an object the provision of a novel method of placing the torpedo at the desired depth below the surface of the water and a novel construction whereby the mine is so placed.

SIGN.—R. C. Lafferty, Clarksburg, W Va. In this case the improvement is in signs, and while the invention has a general application and is capable of general use it is especially designed for use as a memorial sign by fraternal and other societies by which to display the names of the deceased members, and as a directory for office buildings.

DEVICE FOR LOWERING LIFE-BOATS.—C. J Christophersen, New York, N Y. This appliance is for use in controlling the lowering of life-boats from the davits of ships or vessels, etc., and the invention has for its purpose to facilitate the launching of the boat and avoid the wearing on the ropes incident to passing the ropes about cleats and permitting them to slip thereon under the weight of the life-boat, as is the usual practice.

APPARATUS FOR VIEWING STEREOSCOPIC OR OTHER PICTURES.—J Richard, 25 Rue Mélingue, Paris, France. The apparatus comprises a horizontally movable carriage carrying a holder or magazine whereby each view in succession is brought into the line of an upright frame which is [illegible] moved vertically [illegible] the eye pieces of the instrument and thereafter returns the view to the holder.

EASEL.—[illegible], New York, N. Y. This invention relates more particularly to that type of easel adapted for use in supporting pictures, mirrors or the like, or for use as the back of small picture frames. One object is to simplify the construction of the hinge or connection between the back plate and the brace, whereby lost motion between the parts will be eliminated, yet they may be moved relatively to each other with minimum friction.

PROCESS OF RECOVERING TIN FROM WASTE.—A. Nodon, 12 Rue de Moulis, Bordeaux, France. The object in this case is to provide an improved process for the recovery of tin from all kinds of tin lead waste, and more particularly from waste tinned plate, waste lead tin alloy and plated goods resulting from the manufacture of metal "tin capsules," "tin foil" and "tin tubes."

MOLD.—J R. Kay, New York, N Y An object here is to furnish a mold for forming monolithic bodies of concrete, cement, and the like, which comprises removable and separable parts which can be easily mounted in position and taken down, and which is fashioned from standard structural members of metal or other material.

Hardware.

SAFETY-RAZOR BLADE HOLDER.—D. Conzekin St. Petersburg, Fla The invention is especially designed for use in stropping the blade and is so formed as to place the edge to be sharpened at the proper angle for the stropping operation The holder is also made in one piece from a blank and presents a simple economically produced and effective holder for the purpose

FARRIER'S IMPLEMENTS.—W Rawalt Blandinsville, Ill. This invention relates to an improvement in farrier's implements, by means of which a horse's hoof may be quickly and properly trimmed. The object is to provide a tool with a chisel and a movable hammer head, whereby the chisel may be more readily operated to trim the hoof.

VIBRATORY DISINTEGRATOR FOR GAS-PRODUCERS.—J J Aston, New York, N Y This invention relates to certain improvements in the manufacture of producer gas and the object is to render practical the manufacture of producer gas from peat The main essential feature involves the disintegrating action on the peat caused by the expansion of the gas occluded in the peat or held within its pores and interstices.

Heating and Lighting.

HEATING APPARATUS.—R. B Smith, Scotland Ontario, Canada. The inventor's purpose is to provide in combination with a boiler or casing, a combustion chamber in connection with the exhaust of an internal combustion engine for complete burning of the gases, and arranged near the bottom of the casing, an exhaust pipe leading from the chamber, having radiating means, as a coil, located adjacent to the chamber and means for introducing water within the casing surrounding the chamber, and radiating means.

LIGHT-CABINET.—C F McClure and W L Sullman, Sullivan, Ill The purpose of this invention is to produce a device which upon the release of a trigger, will ignite a piece of absorbent cotton or similar material, and permit it to move by gravity along a wire or other suitable guiding means to a place where the illumination or combustion is desired

LAMP-CHIMNEY.—G H Lee, Omaha, Neb. This invention relates particularly to means for centering the chimney of a lamp when it is set in position An object is to provide a chimney having means which will facilitate its being guided to its proper position on the burner without necessitating the exercise of great care

Household Utilities.

SELF HEATING FLAT IRONS.—C. S. Konigsberg and W Allen, Oakland, Cal. This invention relates to irons adapted to generate the vapor or gas by which they are heated. One object is to produce an iron adapted to use denatured alcohol and the like for the heating agent, and having a supply tank formed in the lower portion of the handle of the iron.

QUILTING-FRAME.—S. S. Russell, Columbia, S. C. This invention is an improvement in quilting-frames, and particularly in folding quilting frames. Means provide for adjusting the frame at any angle; provide for securing the extension bars in any adjustment desired and permit them to slide in adjusting relatively to the main bars, and provide for operating to draw the uprights toward each other to securely brace the frame when in use, and also to separate the frame for convenience in storage and shipment.

Machines and Mechanical Devices.

PLUNGER MECHANISM FOR OIL-WELLS.—L. R. McCarthy and J C. Vroman, Spartansburg, Pa. This improvement pertains to the construction and operation of oil wells and the like, and concerns itself especially with the construction and operation of the plunger mechanism. The purpose is to provide a construction for controlling the pawls which lock the collar in the pipe.

SAW-CARRIAGE.—P J Murphy, Alexandria, Va. This device, while permitting the easy manipulation of the saw-carriage, and the adjustment of the stick of wood to the proper length, prevents the saw from coming in contact with the operator's hand. The guard may be raised or lowered to any convenient height and retained in position to permit adjustment of the wood in place for sawing.

ETCHING-MACHINE.—H [illegible], New York, N Y This invention has reference to etching-machines of the type in which a plate or other article to be etched is exposed to the action of free acid in a trough The invention causes the acid to produce a maximum effect and yet prevents the actual contact of the paddles with the surface to be etched

GRIPPER FOR PRINTING-PRESSES.—M. W Alger and C. L. Jacobson, Benton Harbor Mich. The objects here are to provide adjustable fingers or grippers having horizontal adjustment to provide fingers to hold the sheet being printed at the top and bottom of the sheet to provide grippers to grasp at intervals the sheet to be printed, and to provide a mechanism simple and economical in construction and efficient in operation

FILLING DEVICE.—J Parish, New York, N Y The aim is to provide in this instance a device by means of which powders crystals or other granular material can be expeditiously and easily introduced into small necked bottles and the like, which requires little effort to operate it, and which fills the receptacles without spilling any of the material which is being introduced into the receptacle.

Prime Movers and Their Accessories.

SPARK-PLUG FOR INTERNAL-COMBUSTION ENGINES.—M Exquem, 101 Boulevard Pereire, Paris, France The invention relates to an improvement in a spark plug with a tubular electrode and a decompression cock for the purpose of producing the cleaning of the plug not by means of the burned gases, but by fresh gases, that is to say by air containing particles of gasolene. It is essentially characterized by the application to the plug of a device to cut off the ignition when the above cock of the spark plug is opened.

Railways and Their Accessories.

CAR DOOR FOR GRAIN COAL, ETC R R Reaveley, Fort William Ontario Canada The construction embodies two doors hinged at the side edges to swing outwardly and forming, when closed, a substantially triangular opening, with the point of the opening at the bottom a third door for closing the opening hinged at the top to swing inwardly and with the two doors removable from their hinges to swing to the outside of the car below the floor or carried within the car to positions removed from the door opening and the third door removable to the top of the car

CAR FENDER.—T J Kilgen, Portland, Ore The purpose of this inventor is to provide novel details of construction for a fender particularly well adapted for use on a street car and that afford a strong automatically operating car fender, which when in position on a car, will positively pick up and support a person struck by the car without doing serious injury thereto.

ELECTROMAGNETIC TRACTION SYSTEM.—G L. Stanbro, and A D Wagner, Norfolk Va The object of the improvement is to provide a surface contact railway system which will have all the advantages of such a system and adapted for street service in cities as well as suburban traffic. Heretofore such systems have not been successful being only applicable to short lengths of track in factory yards and the like

SEAL-LOCK.—E. L. Pitts Yuma Ariz. Ter In this instance the improvement is in seal record devices The object of the invention is to provide a device for use on railroad freight cars, registered mail sacks etc whereby a continuous and permanent record of the times the car is opened and closed may be obtained.

Pertaining to Recreation.

FISH HOOK.—W E. Koch Whitehall, N Y The invention relates to hooks of the gang type such as shown and described in Letters Patent of the U S., formerly granted to Mr Koch The aim is to provide a hook arranged to dispense with the lead weight on the main hook and to counterbalance the hook with a view to securely holding the live bait floating in a natural position, and to keep the main hook and gang hooks in proper relation to each other

Pertaining to Vehicles.

LOG-WAGON.—W M. Norris, Edwards, Miss Log-wagons require to have great strength and durability along with maximum lightness and easy draft, besides being adapted to turn in a comparatively small circle Eight-wheel wagons are preferable but they have certain objections or defects which this invention removes by improved construction arrangement and combination of the parts.

WAGON DUMP.—E. Ewel, Grand Island, and S. L. Clement, North Loup, Neb. This improvement is particularly adapted for side dump wagons, and means are provided whereby the main chute will receive and support the wagon body when the latter is in dumping position, and means for holding the chute at such time in discharging position and for releasing it from such position after the load is dumped.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper

Notes and Queries.

HINTS TO CORRESPONDENTS.

The full name and address must accompany all letters, or no attention will be paid thereto. This is solely for our information *All* queries are answered by mail, and a *few* of the selected answers are afterward published in the paper We cannot undertake to furnish information on matters of personal interest without reasonable compensation To answer questions which are not of general interest usually costs us from $2 00 to $3 00 each upward, and this sum should invariably be remitted in such cases. When there are questions involving building or other construction or when calculations must be made an estimate of the cost will be furnished upon request We cannot give answers to examination papers or decide wagers, nor can we undertake to solve mathematical problems of any description whatsoever Do not use postal cards.

Queries from this vicinity not answered within fourteen days should be repeated in full Queries from points more remote will require a longer time

We do not make chemical analyses but we are always pleased to give the names of minerals which are submitted to us, when it is possible for us to do so. The minerals should be sent marked distinctly with the name of the sender, and should be sent fully prepaid.

Buyers wishing to purchase any article not advertised in our columns will be supplied with the addresses of the houses manufacturing or carrying the same as soon as possible, or if we are unable to do so, their queries can be advertised in our special classified column

Any books on any scientific or technical subject can be furnished We solicit requests for quotations. The Scientific American Supplements referred to are mailed for ten cents each. Book and Supplement catalogues will be sent free on request A careful reading of these "Hints to Correspondents" will prevent any misconception as to the uses and will prevent abuses of this column.

(12148) R. H A. says I tried the experiment of renewing old dry cells and proved to be a failure which was on page 300 of the October 23rd issue The chemical did not want to absorb and took two days before I was able to get the right quantity into the battery, and when sealed up tested about 7 amperes. Will you please tell me how I may overcome this trouble and just how to do it? A We have nothing better to offer for the renewing of dry cells than you already have tried. It is not worth the while to renew these cells The liquid is very slowly absorbed and the cell is already full of crystals from the last charge, which are the result of the action and which will not dissolve in the liquid which you put into the cell For these reasons one does not get much current from a renewed dry cell We publish all such processes for the reason that many amateurs like to experiment with any such process and they get much pleasure out of the work Probably your result was as good as could be expected.

(12149) F M R says Is it ever possible that a stone will never reach the bottom of water in midocean which may be, let us say 25 miles deep? That is is water ever so compressed that a stone will displace a volume of water which at this great pressure is equal to the weight of that stone? To state the same question in a different way Would a submarine diver require heavier shoes to go down 100 feet than he would to go down 20 feet? Allowing of course for the added buoyancy of the longer air pipe A Water is one of the most incompressible of materials, far more so than the hardest steel It follows from this that a substance which is denser than water at the surface of the ocean will never become lighter than water as it sinks, or that water will never become as dense as this substance at any depth, since the substance will be compressed more by sinking in the water than the water has been at any level under the water You will find a full discussion of this question in the following numbers of the Scientific American Vol 96, Nos 9 13 and 19, in Answers to Queries We will send the three papers for 10 cents each

(12150) E. D says Would you please tell me what weight of wire should be used on the fields of the simple electric motor described in Experimental Science Vol I page 407 for shunt winding using single cotton covered wire? Please state also the length of wire on each coil of the fields. A We have no additional data for the simple electric motor beyond what is given in Experimental Science or in Supplement No. 641, in which the plans for this motor were originally published. If you connect the motor in shunt it will doubtless run with battery designed for it and described in Supplement No 792 We send all Supplements at 10 cents each. With this battery the current is graduated by varying the immersion of the plates and thus economy of action is secured

(12151) E. H. H. asks how a blue print can be changed to black. A A blue-print can be changed to a black color by placing the print into the following solution Borax ¼ ounce, water 6 ounces. When black and wash the print and place it into the following solution Gallic acid ¼ ounce tannic acid ¼ ounce, water 8 ounces As soon as the color is attained wash the print and dry A second blue print can be made from this of course reversed as to position of lines or figures but by placing the back of the changed blue print against the surface of sensitized blue-print paper a duplicate with blue lines can be obtained.

NEW BOOKS, ETC.

Fundamental Principles of Chemistry. An Introduction to All Textbooks of Chemistry By Wilhelm Ostwald Translation by Harry W Morse. New York Longmans, Green & Co., 1909 8vo, pp 349

Prof Ostwald's name is one to conjure with in almost every branch of science and in chemistry particularly It would be difficult indeed to mention a chemist who has contributed more to the advancement of his science in our time or one who occupies a more eminent position as a teacher In this book Prof Ostwald has presented with remarkable ingenuity and simplicity the actual fundamental principles of the science of chemistry their meaning and connection and stripped them so far as possible of irrelevant additions. The book may be regarded as an attempt to work out chemistry under the form of a rational scientific system without bringing in the properties of individual substances Hence it has been necessary to restate elementary principles in a new light, and to bring out many new connections in regions hitherto untouched That is why this work will be found different in its treatment from any other work on chemistry that has ever been written The pedagogic value of the preceding can be judged only by the instructor of chemistry But to anyone familiar at all with chemistry, its merit must be apparent from an impartial consideration of the book.

A Hand Book of Practical Calculation and Application of Reinforced Concrete. Kahn System Standards Compiled and published by the Engineering Department of the Trussed Concrete Steel Company 12mo, 126 pp

The rapid growth of reinforced concrete construction makes necessary a hand book on design similar to those in use for the ordinary classes of building material The object of this hand book is to present to the designer tables and information in such form as to be made immediately available for use in actual designs and at the same time to have these tables founded on scientific formulæ approved by our best engineering practice The work as presented deals mainly with the Kahn trussed bar The Kahn system of reinforced concrete however uses in its application several other types of reinforcement including rib metal, hy rib cup bars column hooping, rib lath, and rib studs.

HOW TO OBSERVE AND RECORD THE WEATHER.

(*Continued from page 412*)

mounted very nearly horizontally These two instruments are usually supported as they appear in Fig 3

The minimum is read and then "set' by raising it gently until the index slides to the surface of the alcohol (Fig 5) The maximum must be lowered to a vertical position before it is read (Fig 4) After this reading is taken and recorded the thermometer is then "set' by gently swinging it up and down until that amount of mercury is shaken back into the bulb that represents the difference in temperature between the maximum and the present if any When no more mercury can be returned to the bulb the thermometer is allowed to hang vertically and a second reading is taken The mercury now gives the temperature at the time of reading, and this reading is recorded as 'set maximum' In other words, the maximum thermometer serves in place of two thermometers. First, it records the highest temperatures during the twenty four hours, and secondly, when it is set, it gives the temperature at 7 P M—the time of reading

Exposure—The marked variation between the readings obtained from thermometers owned by private persons and Weather Bureau thermometers is due much more frequently to the difference in the manner of exposing them than to difference in quality accuracy, or cost price Thermometers exposed against buildings, on verandas in windows, cannot often be trusted to give even approximately the true temperature of the atmosphere For the air is not a stationary body but is a continuously intertwisting expanding and contracting gas perpetually seeking an equilibrium which is seldom even momentarily gained than it is instantly lost All gross inaccuracies attending exposure of thermometers are overcome by the shelter adopted by the Weather Bureau and provided to all observers (Fig 9)

The outside dimensions are 42 inches long by 36 inches wide by 30 inches least height, and a second roof 6 inches above, has two ends open. The air has free access to the interior, for the four sides of the shelter are louvered; that is, composed of shutters. These shutters overlap, and have a pitch which enables them to shed water, and intercept also the rays of the sun, even when level at sunrise or sunset.

Shelters ought to be placed in a large open space, or upon a house top or other high building, where the circulation of the air is unimpeded Correct temperatures are recorded only when the air flows freely round the shelter as well as through it When the shelter cannot be situated in an open area, it may be set up on the north side of a building, with a space not less than four inches intervening.

Sunshine does not give the average temperature of the air, but the highest, and so a thermometer, hung in the sun, falsifies or greatly exaggerates. If the temperature is 87, a thermometer in the sun will run up to 100 or more The confiding observer, suddenly aware how hot it apparently is, grows faint from the imaginary heat, runs for a fan, and rapidly raises his bodily temperature by his vigorous gesticulations trying to cool himself.

Instruments that measure the depth of the fall of rain are neither well known by sight, nor is the method by which they record the rainfall very familiar

Fig. 7 shows the essential parts of a rain gage which are a receiver a measuring tube, and an overflow The rain is caught by the receiver, the bottom of which is funnel shaped, and falls into the measuring tube Should the amount that falls be excessive, and more than fill the measuring tube, the excess overflows into the outer cylinder The rain gage is designed to catch the precipitation of rain and to facilitate the reading of the amount by mechanically magnifying the quantity The diameter of a Weather Bureau rain gage receiver at the top is 8 inches, the diameter of the measuring tube is 2 53 inches. In consequence of this difference in area, the water in the measuring tube stands ten times deeper than if spread over the area of the receiver, so that a rainfall of one inch in the receiver stands ten inches in the measuring tube. The scale by which the water is measured is graduated in hundredths of an inch, but that inch on the scale is really ten inches long (Fig 8)

In the normal temperate climate, there are only a few rains in a year when a reading of one inch is observed A fall of rain amounting to two inches is uncommon a precipitation recording three or more inches is the exceptional record of a decade or two Some rains, attended by strong wind vivid lightning and apparently heavy downpouring of sheety rain, give a reading as low as twenty five to sixty or seventy hundredths of an inch, while other rains, not so accompanied by electric phenomena and aerial disturbances, occasionally give a reading of an inch or more. Only an experienced observer is competent to make a fairly close guess of the amount of precipitation, and at best his guess is subject to the errors that so commonly invalidate all suppositions.

Snowfall is caught in the large cylin-

Two Good Books for Steel Workers

Hardening, Tempering, Annealing and Forging of Steel
By JOSEPH V. WOODWORTH
Size 6½ x 9½ inches. 288 pages. 201 illustrations. Price $2 50 postpaid
THIS is a practical work treating clearly and concisely modern processes for the heating, annealing, forging welding, hardening and tempering of steel, making it a book of great value to toolmakers and metal-working mechanics in general. Special directions are given for the successful hardening and tempering of steel tools of all descriptions, including milling cutters, taps, thread dies, reamers, hollow mills, punches and dies and various metal-working tools, shear blades, saws, fine cutlery and other implements of steel, both large and small. The uses to which the leading brands of steel may be adapted are discussed, and their treatment for working under different conditions explained; also special methods for the hardening and tempering of special brands. A chapter on case-hardening is also included.

The American Steel Worker
By E. R. MARKHAM
Size 5¼ x 8 inches. 367 pages. 163 illustrations. Price $2 50 postpaid
THIS is a standard work on selecting, annealing, hardening and tempering all grades of steel, by an acknowledged authority The author has had twenty-five years' practical experience in steel-working, during which time he has collected much of the material for this book. Careful instructions are given for every detail of every tool Among the subjects treated are, the selection of steel to meet various requirements; how to tell steel when you see it; reasons for different steels; how to treat steel in the making of small tools, taps, reamers, drills, milling cutters; hardening and tempering dies, pack-hardening, case-hardening; annealing; heating apparatus; mixtures and baths, the best kind, and why; and in fact everything that a steel-worker would want to know is contained in this book.
OUR SPECIAL OFFER: The price of these books is $2.50 each, but when the two volumes are ordered from us at one time, we send them prepaid to any address in the world on receipt of $4.00.

Just Published—A BOOK OF INTEREST TO RIFLEMEN

The Bullet's Flight from Powder to Target

The Internal and External Ballistics of Small Arms. A Study of Rifle Shooting with the Personal Element Excluded, Disclosing the Cause of the Error at the Target.

Illustrated with one hundred and eighty-eight plates, showing the results of over three hundred rifle experiments performed and chronologically arranged

By F. W. MANN, B.S., M.D.

Size 7½ x 9¾ inches. 384 Pages. Price $4 00 postpaid

THIS is a thoroughly practical treatise and deals with a subject the literature of which is not commensurate with its importance or interest, and it possesses unusual value, not only because it furnishes a large amount of information, of a very practical kind, but because this information is the result of a practical experience on the part of the writer, extending over a period of thirty-eight years. The results of the author's experiments, as here given, have been persistently and laboriously worked out with an earnest desire to assist his fellow marksmen. In view of the fact that conjecturing and theorizing have been so prevalent in rifle literature, the work has been kept free from speculation, except where they have either been proved to be false or have been fully substantiated by recorded experiments. Most of the illustrations are photographic reproductions of the results of actual tests. Every page is full of interest for the rifle enthusiast. There is a full discussion of various kinds of rifles, of the effect of difference of length, of variations of rifling, etc. as well as of instructive experiments such as that of venting the barrel near the muzzle. An idea of the contents may be gathered from a few of the subjects treated, such as the Personal Element vs. Mechanical Rifle Shooting; Utility of Vented Barrels; High-Pressure Sharpshooting Powders; Telescope Mounts; Ruined Rifle Bores vs. Smokeless Powder vs. Primers; Accurate Ammunition Difficulties; Flight of Bullets; Gyration and Oscillation; Motions Executed by Normal Flying Bullets; Determining Rifle Twists; Kinetics of Spin, etc. In many respects this work is unique in the literature that has been published on this subject. It is a thoroughly practical work and will be found to be of very real value to those who are engaged in a study of the ballistics of the rifle with a view of improving the all-around efficiency of that weapon.

MUNN & COMPANY, Inc., Publishers, 361 Broadway, New York City

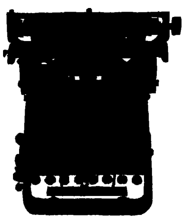
Special Limited Scientific American Offer

Saves You $65 100 Model 8 Send No Money Now

American Typewriters

This special offer gives you a high grade Typewriter at $35, the lowest price at which a standard machine has ever been sold, and on easy terms. The American will do the work of the $100 machines at high speed and is covered with the same guarantee. You save $65. It is their equal because it has every essential feature, 1200 cumbersome, troublesome and easily broken parts of the other machines have been eliminated. The absence of all these complicated parts makes the American tip the scales at 12 pounds. It's the only high grade machine that is really portable. The fundamental point of American superiority is the single type-bar-one-piece of steel-non-bendable and unbreakable by any stroke that can be delivered on the key, and this is the cause of its simplicity, durability efficiency and compactness.

FIVE DAYS' FREE TRIAL Don't buy the American on our mere say so, fill out the attached coupon and mail it to us at once. We will ship you an American F. O. B., N. Y. Use it in your office, give it the severest test you can. Don't delay simply fill out and mail the coupon with references. Specify the style of type you wish and if you wish a hard platen for manifolding.



American Typewriter Company, 265 Broadway, N. Y Incorporated 1893.

Please ship me for 5 days' free trial, one latest model American Typewriter offered in the Scientific American, the regular price of which is $100. I authorize you to do this with the understanding that, if I am not satisfied—if the machine is not satisfactory to me, I am to notify you within 5 days to that effect, and hold same subject to your order or deliver it to the express agent carefully packed as you may direct, or if I desire to keep it, I am to pay $5 after 5 days and $5 per month until the full special price of $35 is paid, machine to remain your property until paid for

der by removing the funnel and tube. It is measured by first melting the snow, then pouring the water into the measuring tube, and ascertaining the quantity exactly as for rain. The measuring tube may be filled to the brim with warm water, and this poured on the snow, which will soon melt. The measuring tube is filled once, and then emptied, the remainder of the fluid represents the precipitation from the snowfall A third way of arriving at the snowfall is to cut a section of snow by turning the receiver down over it where the snow is level and not blown away nor drifted by wind. The section is then carefully lifted by a small shovel or paddle board, melted and measured To learn approximately the depth of water in a snowfall one-tenth of the thickness of the layer of snow is taken, ten inches of snow being estimated to contain one inch of water but this gives too little if snow is wet

Exposure of Rain Gage —It will not do to set up a rain gage anywhere and expect to get exact measurements of precipitation for the rainfall varies as much as thirty per cent below the normal according to location owing to the action of wind currents, to the intervention of buildings trees or fences unduly near the gage A roof must be at least sixty feet square, and level ere the wind action on the side walls of a building is eliminated from influencing the rain gage in the center

Wind brakes are desirable around an instrument, the rule being that obstructions must be removed a distance equal to their height For this reason, a fence surrounding a rain gage four feet high and four feet away, will favorably overcome the wind so that on a large open space more water will be caught by the receiver For it is to be understood that the fluctuations of amounts caught between two rain gages near each other is to be ascribed to the wind Consequently, rain gages protected at a suitable distance from the violence of the wind by bushes fences, trees or buildings catch more water than unprotected rain gages. This may be attributed partly to side currents whirling near the ground and partly to the splashing of the drops of rain if they strike the gage through these intertwisting ground currents (Fig 10)

River Gages —A river gage is a scale by which the height of water in a stream may be measured, and the stage of water, whether low or high, may be observed and recorded The Weather Bureau endeavors to get reliable data of all streams that affect inland navigation It so happens that it is sometimes important to receive reports of the condition of the upper reaches of certain tributaries that are themselves unnavigable but whose flooding may seriously imperil towns below, and materially swell the high water of the navigable rivers into which they empty

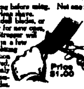
A river gage can be a simple contrivance, and answer all practical purposes for creeks and small rivers A graduated board extending below the lowest known level fastened against a bridge abutment is unexcelled if it be convenient to read it at all times The stone facing of an abutment itself may be smoothed and graduated and be made to answer almost as well as an elaborate device (Fig 6)

Strips of brass or of lead securely inset or marks burned in, will do for graduations The "feet" should be plainly numbered lest in reading the gage when the water is very high, a mistake is made Great care must be exercised to graduate the sloping timbers of this style of gage for which nothing less than an engineer's level is sufficiently accurate for governmental requirements. The illustration explains how this may be done with a carpenter's level

The book in which the observations are written is called the "Meteorological Record" The pages of this record are ruled for date, maximum minimum range set maximum, precipitation prevailing direc-

(*Concluded on page 420*)

A Clean Shave



All new blades need stropping before using. Not one in ten comes sharp enough for a clean shave.

Why scrape your face with dull blades, or continue to throw away money for new ones, when the Gaylor Automatic Stropper will resharpen all your dull blades in a few moments, giving them a hairsplitting edge better than new. The motion is automatic, no practice required, a child can use it. It is the only stropper in the world that successfully sharpens double-edge blades.

Price $1.00

In case with barbers' genuine Horse Hide Strop, $2 00

Order through your dealer. Or will send postpaid on receipt of price. Be sure to state for what make of Blade. Money willingly refunded if not entirely satisfactory. Write for descriptive circular. Agents wanted.

tion of the wind, character of the day, and remarks.

Opposite the date is set down the reading of the highest and lowest temperatures, the difference is placed in the range column, the set maximum, as explained above, is the temperature at the time of reading. The time of beginning and the time of ending, with the amount of precipitation, is next entered in the record. The prevailing direction of the wind is that direction from which the wind blows the most hours of the twenty-four. The character of the day refers to the sky, whether it is cloudy, partly cloudy or clear. A sky of 70 per cent freedom or more, from clouds is said to be "clear", 50 to 60 per cent without clouds, is called "partly cloudy", none to 20 per cent without clouds is accounted "cloudy". In the column for remarks may be entered notes descriptive of unusual phenomena, such as severe storms, meteors, killing frosts, remarkable depths of snow, floods in the streams of the vicinity, aurora borealis, deaths by lightning. To make the record valuable by the uniformity of its keeping, it is highly important that the readings be taken at the same hour each day, preferably at 7 P. M., seventy fifth meridian time. A column for the water gage may be added, if the levels of a stream are to be observed.

TESTING THE MAN-ENGINE.

(Continued from page 418)

is gaged by another attachment electrically joined to this clock. At the height of the subject's shoulder are arranged, upon a bar, two small hinged uprights. His hand is placed against one of these little posts and he is told to move it as quickly as possible in the direction of the other and to knock both of them down in the least possible time. The clock measures the time interval between the fall of the two uprights, and thus it is possible to time the swiftest movement of the arm in passing through a yard or foot of space. Men are found to be twice as rapid in this movement as women; Indians much slower than whites, negroes more constant than whites in rate of movement.

Another ingenious man-engine gage is a cylinder revolved by clockwork and covered with paper against which rests a marking point moved by air pressure exerted through a tube connecting with any number of attachments. This apparatus is used largely in comparing the workings of the body while under normal conditions and during hard thinking or strong emotion, or after great intellectual or physical effort. Thus when we

THE WELCOME GIFT FOR MEN

Patented Dec. 31, '06. Other Patents Pending.

50 Sargent Perfectos . . (Regular Price $3.50)
Sargent Patent Cigar Chest (Regular Price $3.50)
$3.50 for Both

You take no risk by buying with our "Money-Back" Guarantee

Every smoker will be glad to get a box of Sargent Cigars. Every man who smokes should have a Sargent Cigar Chest to keep his cigars in prime condition. The two together at the price of one is an offer hard to resist It is the ideal Christmas gift for men

Sargent Cigar Chest FREE

The Sargent Patent Cigar Chest (shown above) is a perfect little cigar store in itself It is made of oak, mission finish, glass-lined and sanitary No pads or sponges to bother with, the moisture being supplied by a new process. With a Sargent Cigar Chest you never lose money on dried-out cigars. The chest will be sent you with your first order and is your property even if you never buy another cigar of us.

OUR "MONEY BACK" GUARANTEE

If cigars and chest are not up to your expectations, send them back at our expense and we will refund your money without question. Send us $3 50 and we will ship you 50 Sargent Perfectos and the Cigar Chest. If you order 100 cigars, price $7 00, *we will prepay express charges on cigars and chest anywhere in the United States.* Subsequent orders for cigars filled at $7 00 for 100; $3 50 for 50.

For $2 00 extra we will send a mahogany chest instead of oak; or for $1 00 extra, one of Circassian Walnut.

Concrete
Reinforced Concrete
- AND -
Concrete Building Blocks

Scientific American Supplement 1543 contains an article on Concrete by Bryson Cunningham. The article clearly describes the proper composition and mixture of concrete and gives results of elaborate tests.

Scientific American Supplement 1538 gives the proportion of gravel and sand to be used in concrete.

Scientific American Supplements 1567, 1568, 1569, 1570, and 1571 contain an elaborate discussion by Lieut. Henry J Jones of the various systems of reinforcing concrete, concrete construction, and their applications. These articles constitute a splendid text book on the subject of reinforced concrete Nothing better has been published.

Scientific American Supplement 997 contains an article by Spencer Newberry in which practical notes on the proper preparation of concrete are given.

Scientific American Supplements 1568 and 1569 present a helpful account of the making of concrete blocks by Spencer Newberry

Scientific American Supplement 1534 gives a critical review of the engineering value of reinforced concrete

Scientific American Supplements 1547 and 1548 give a resume in which the various systems of reinforced concrete construction are discussed and illustrated.

Scientific American Supplement 1564 contains an article by Lewis A. Hicks, in which the merits and defects of reinforced concrete are analyzed.

Scientific American Supplement 1551 contains the principles of reinforced concrete with some practical illustrations by Walter Loring Webb.

Scientific American Supplement 1573 contains an article by Louis H Gibson on the principles of success in concrete block manufacture, illustrated.

Scientific American Supplement 1574 discusses steel for reinforced concrete.

Scientific American Supplements 1575, 1576, and 1577 contain a paper by Philip L. Wormley, Jr on cement mortar and concrete, their preparation and use for farm purposes. The paper exhaustively discusses the making of mortar and concrete, depositing of concrete, facing concrete, wood forms, concrete sidewalks, details of construction of reinforced concrete posts.

Each number of the Supplement costs 10 cents.

A set of papers containing all the articles above mentioned will be mailed for $1.80.

elastic belt placed about the chest is connected with the apparatus, the marking hand will record upon the paper the expansion and contraction due to breathing. Arthur MacDonald, an anthropologist of Washington, has used this instrument in studying the influence of intellectual and emotional states upon breathing and has found that, in general, concentration of thought, as in mathematical calculations or in reading, considerably decreases the breathing. Inasmuch as a falling off of oxygen in the blood results from decrease of respiration he suggests that this may partly explain the proverbial thin blooded condition of deep students Prof Hugo Münsterberg of Harvard, finds with such an apparatus that sudden pleasure makes the respiration weaker and quicker, displeasure, stronger and slower, excitement, stronger and quicker, acquiescence, weaker and slower A similar apparatus when attached to the wrist writes a record of the pulse-beats, showing that pleasure heightens and retards them, displeasure weakens and accelerates them, and that excitement strengthens and quickens them

There is connected to the same recording instrument a device having two rods which press between the lips and transmit a record of their slightest movements to the paper upon the revolving cylinder Similar gages keep score on the movements of the larynx soft palate, and tongue and thus are all of the physical elements of voice measured while various emotions are being experienced

In one of these laboratories, an instrument when attached to the hand, measures its involuntary movements in three directions—forward and backward from right to left, or upward and downward those three elements being recorded upon one revolving cylinder by a separate marking point Experiments with this device indicate that the hand unconsciously follows the direction taken by the mind When the subject commences to obey instructions to concentrate his mind on some object above or below or to his right or left the record paper shows that the hand has been moved in the direction of that object One test used by Prof Münsterberg is to ask the subject to think attentively of a special letter of the alphabet and then spread in a half circle about the instrument cards bearing these letters The average subject s hand will quickly record an impulse toward the letter of which he is thinking though he is unaware of it Thus it will be seen that whither the mind leads the hand will follow unwittingly, and here we have an analysis of gesture and also of the phenomena of "planchette and "oulja board,' as well as of the old time parlor game of "mind reading"—really muscle reading

These man-engine gages are revealing many other hitherto hidden truths concerning the mind s unconscious control of the body's movements and actions and perhaps the prettiest demonstration of this is given by a device consisting of a great tray containing a man lying flat upon his back and balanced upon two knife blades at such a delicacy of poise that the least movement sets the tray to see-sawing The subject is so placed that his center of gravity rests over the blades and so long as he relaxes his mind and holds his breath a spirit level shows that the tray rests in a horizontal plane, but as soon as he commences to breathe it commences to rock itself in cadence with his inspirations and expirations When the subject, in response to a command, commences to solve a problem in mental arithmetic the end of the tray toward his head sinks and that holding his feet rises, all of which indicates that when there is any call for special activity of the brain the blood rushes to that organ, as if to nourish thought. But now if the subject relax his mind as before the tray will again balance horizontally Next a little device which rapidly revolves two mirror-studded panels is placed before his eyes and may so fatigue

Just a Common
Job

Just a common job means just a common salary

Imagine for a moment that from twenty to forty years have been added to your life—that you have reached the age of fifty or sixty

What are you doing to-day that will enable you to forecast something better for this later period than just a common job and a common salary?

Only one class of men are absolutely sure of being able to maintain their full earning capacity after fifty These are the trained men—men who have fortified themselves in youth against the common job problem which confronts the untrained man at any time in life

Why not give yourself the advantages of something better than a common education and insure against the common job problem before it is too late and you have lost ambition?

Don t give old age a chance Let the American School train you so your services will be desired and sought after—not endured or overlooked

Fill in and mail us the coupon. Let us tell you how you can qualify for the position to which you aspire in either the great fields of Engineering or Business

Lubrication Costs Less Than Repairs

Most of the bills for automobile repairs are really the costs of faulty lubrication in disguise The grade of Vacuum MOBILOIL specially prepared for your particular car will give perfect lubrication and save time trouble and money

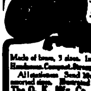
VACUUM
MOBILOIL

is made in six different grades One of these is the right grade for you The requirements of your car have been exactly determined and this grade of MOBILOIL prepared for it with scientific precision

Send for booklet listing every automobile made and the grade of MOBILOIL prepared for it. Thereafter you need only wat h th label on the can, the car will take care of itself The book is free Its facts on the science of lubrication are invaluable. Gives track records to date and other pointers.

MOBILOIL, in barrels and in cans with patent pouring spout is sold by dealers everywhere. Manufactured by

VACUUM OIL CO.,
Rochester, N. Y.



75,000,000 "O.K" PAPER FASTENERS

SOLD the past YEAR should convince YOU of their SUPERIORITY

They Add TONE to Your Stationery in the Office Bank, School or Home.

Easily put on or taken off with the thumb and finger. Can be used repeatedly and "always work"

Made of brass, 3 sizes. In brass boxes of 100

Handsome. Compact. Strong. No Slipping Never!

All stationers Send 10c for sample box of 50, assorted sizes. Illustrated booklet free.

The O. K. Mfg. Co., Syracuse, N. Y. No 1B

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES

WANTED. Manufacturer of enamel ware to manufacture a useful patented article on royalty basis. Mrs Sarah W Hitchcock, [illegible] E. [illegible] St., Dixon, Ill.

Inquiry No. [illegible].—For manufacturers of "[illegible] Electro-Catalytic Sparking Plug."

PATENTS FOR SALE.

FOR SALE.—Patent No. [illegible]. A spring wheel to substitute the rubber-tire wheels actually used for automobiles. Address Luis I. Leon, San Juan, Porto Rico.

Inquiry No. [illegible].—Wanted, the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

FOR SALE. Patent No. [illegible]. An improved lathe rest for holding cylinders while being bored in an engine lathe. For further particulars address A. E. Whiting, Weston, W. Va.

Inquiry No. [illegible].—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE.—Patent No. [illegible]. Shock cushioning neck yoke. Something new, nothing of the kind on the market. Sell outright, reasonable. Address William Kleinaschay, Campbellsport, Wisconsin.

Inquiry No. [illegible]. For information regarding shoes not made of leather but similar to the same and are as durable.

DO you want to manufacture electric heaters? The best patent that ever was issued in the United States is No. [illegible], for sale. Write Moise Landry, Hotel Carolyn, Turlock, Cal.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE.

THE SANBORN BAG LIFTER. A device to assist in handling bags of grain, cement, etc. Saves the farmers and avoids damage to bag. Sample sent free on request. H. & E. Sanborn, Portland, Maine.

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

FOR SALE.—Engine lathe, swings 9½ in., takes [illegible] in. between centers. Complete with full set change gears to cut all pipe threads, [illegible] to [illegible] in. Price only $[illegible]. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. [illegible]. Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

FOR SALE.—An Alvin Clark 4-inch Equatorial Telescope, 5 eye pieces, prism, sun glass and tripod. Cost $[illegible]. Sherman, [illegible] East [illegible]th Place, Chicago, Ill.

Inquiry No. [illegible].—Wanted, address of rubber manufacturers in Germany.

FOR SALE.—Patent [illegible]. Improvement on pipe wrench. Simple in construction and automatic. For full information, write A. C. Pearson, Attorney, [illegible] Virginia Avenue, Indianapolis, Ind.

Inquiry No. [illegible].—Wanted, to buy a washing machine that is run by a coil spring motor.

TYPEWRITERS.

REAL REMINGTON $[illegible].—One machine only in new localities to secure desirable agent. Special agents prices supplied on all makes of typewriters. [illegible] ribbons $[illegible]. Standard Typewriter Exchange, [illegible] Park Row, New York.

Inquiry No. [illegible]. Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

MISCELLANEOUS

"LIGHT, HEAT, MAGNETISM AND ELECTRICITY are all one and the same thing." If you want to know what they are, send fifty cents for a copy of this pamphlet to A. V. Howland, El Paso, Texas.

Inquiry No. 9034.—For manufacturers of machinery that could reduce stumps to kindling wood.

WANTED.—Designs for a successful single pulley drive for adaptation to machinery tools. Address A. H. Anderson, 79 Dearborn Street, Chicago, Ill.

Inquiry No. [illegible]. Wanted the address of the manufacturers of "Cycle Ball Bearing Suspenders."

HAIR GROWS when our Vacuum Cap is used a few minutes daily. Sent on 60 days free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., [illegible] Barclay Block, Denver, Colo.

Inquiry No. [illegible].—Wanted the address of the Chapman Electric Purifying Co.

LISTS OF MANUFACTURERS

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. [illegible].—Wanted the address of Farney Safety Razor Co.

A LIST OF 1,[illegible] mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. [illegible]. Wanted the address of the manufacturers of mirrors that are transparent when the light in the rear is stronger.

Inquiry No. [illegible]. Wanted to buy outfits necessary for agate polishing.

Inquiry No. [illegible]. Wanted the address of the International Lumber and Development Co., manufacturers of hardwood.

Inquiry No. [illegible]. Wanted machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

Inquiry No. [illegible].—Wanted, the address of parties who install plants for making oxygen or ozone gas.

Inquiry No. [illegible]. Wanted, address of manufacturers of metal table slides for extension tables.

Inquiry No. [illegible].—Wanted to buy rotary brushes suitable for a shoe shining machine.

Inquiry No. [illegible].—Wanted, to buy equipment for manufacturing starch and denatured alcohol from potatoes, also manufacturers of equipments for vegetable canneries.

Inquiry No. [illegible].—Wanted to buy machinery for extraction of cotton seed oil on a small scale.

them that sleep will cause. If so the end of the tray holding his head will rise and that holding his feet will fall, showing that in sleep the blood leaves the brain for the extremities. For a somewhat similar purpose is a large glass jar holding the arm, submerged in water. When any action of the mind causes the blood supply of the arm to increase or decrease—as the vital fluid is attracted toward or repelled by the brain—a marking point resting upon the paper of the moving cylinder above described is raised or lowered. With this has been determined that every emotional excitement speaks in the blood supply of every limb.

How our states of mind unconsciously alter, also our powers of performing muscular work, are nicely demonstrated by a machine attached to the middle finger, generally accepted by physiologists as the index to the body's muscular tone. A vise holds the forearm and hand outstretched, palm upward, upon a table, and the finger is harnessed to a cord hanging over a pulley and suspending a weight. As the finger is bent and straightened it raises and lowers the weight and at the same time a recording point worked by the cord keeps score upon a revolving cylinder. It has been discovered that if the subject concentrates his mind upon the effort of thus contracting his finger frequently and each time raises the weight with his utmost force, his finger will weaken and after a time will scarcely stir the weight. But if he continues to make this effort regardless of the results—without worrying about them—sooner or later the strength of the finger will begin to return and will move the weight almost as much as before. Thus he will continue with alternate periods of fatigue and almost complete recovery—a phenomenon akin to that of the athlete's "second wind." The experiment plainly demonstrates how fear of the results of effort will wear upon the muscles with which the effort is made.

Among the most important of the gages which measure a man-engine's comparative powers of self-direction are those which record the acuteness of the senses—of those telegraph systems over which are dispatched, from the various objects to consciousness, the subtle messages upon which our total impressions of perceived objects are based—the raw material, in fact, out of which our every thought is *manufactured.*

Acuteness of hearing is tested by a device in which balls of cork fall a certain distance upon a plate of glass, the ear being distant so many inches. At the outset of this test the height from which the balls fall is so slight that the ear does not perceive their impact, but the length of drop is gradually increased until the sound commences to be audible. The acuteness of each ear is measured upon a scale in units of the length of drop at which perception of the sound just barely commences. Then there is a gage measuring the ear's estimate of direction. A graduated horizontal circle surrounds the head and after the subject has been blindfolded a sound is made with a telegraphic sounder moved to the different degrees marked in the circle. The subject's estimates of the direction whence the sound issues are compared with its actual direction.

Acuteness of seeing is measured by devices too numerous for description. One of the most interesting exposes a long black surface across which extend three movable white strips. Two are placed a certain distance apart and the third, moving automatically, is stopped by the subject at the point which he estimates to be exactly between the others. A concealed scale shows his error.

When his acuteness of smell is tested the subject sits before an instrument from which protrude into his nostrils a pair of tubes connecting with a metallic case shielded from his eyes. The examiner fits *to the open end of the* tubes various cylinders filled with substances of different perfume, whose strength varies

(*Concluded on page [illegible].*)

Three New Interesting Books

The Scientific American Boy at School

By A. RUSSELL BOND

12mo. 338 Pages. 314 Illustrations.
Price $2.00 postpaid.

THIS book is a sequel to "The Scientific American Boy," many thousand copies of which have been sold, and has proven very popular with the boys. The main object of the book is to instruct how to build various devices and apparatus, particularly for outdoor use. The construction of the apparatus, which is fully within the scope of the average boy, is fully described and the instructions are interwoven in an interesting story, a feature which has assisted in making the "Scientific American Boy" so popular with the boys.

It takes up the story of "Bill" and several of his companions at boarding school. They form a mysterious Egyptian society, whose object is to emulate the resourcefulness of the ancients. Their Chief Astrologer and Priest of the Sacred Scarabeus is gifted with unusual powers, but his magic is explained so that others can copy it. Under the directions of the Chief Engineer, dams, bridges, and canal-locks are constructed. The Chief Admiral and Naval Constructor builds many types of boats, some of which are entirely new. The Chief Craftsman and the Chief Artist also have their parts in the work done by the Society, over which Pharaoh and his Grand Vizier have charge. Following is a list of the chapters.

Chapter I, Initiation; Chapter II, Building a Dam; Chapter III, The Brig; Chapter IV, The Lake House; Chapter V, A Midnight Surprise; Chapter VI, The Modern Order of Ancient Engineers; Chapter VII, A "Pedal Paddle-Boat"; Chapter VIII, Surveying; Chapter IX, Sounding the Lake; Chapter X, Signaling Systems; Chapter XI, The Howe Truss Bridge; Chapter XII, The Seismograph; Chapter XIII, The Canal Lock; Chapter XIV, Hunting with a Camera; Chapter XV, The Gliding Machine; Chapter XVI, Camping Ideas; Chapter XVII, The Haunted House; Chapter XVIII, Sun Dials and Clepsydras; Chapter XIX, The Fish Tail Boat; Chapter XX, Kite Photography; Chapter XXI, Water-Kites and Current Sailing; Chapter XXII, The Wooden Canoe; Chapter XXIII, The Bicycle Sled; Chapter XXIV, Magic; Chapter XXV, The Sailboat; Chapter XXVI, Water Sports, and Chapter XXVII, A Geyser Fountain. Index.

Handy Man's Workshop and Laboratory

Compiled and Edited by A. RUSSELL BOND

12mo. 467 Pages. 370 Illustrations.
Price $2.00 postpaid.

EVERY practical mechanic, whether amateur or professional, has been confronted many times with unexpected situations calling for the exercise of considerable ingenuity. The resourceful man who has met an issue of this sort successfully seldom, if ever, is averse to making public his methods of procedure. After all he has little to gain by keeping the matter to himself and, appreciating the advice of other practical men in the same line of work, he is only too glad to contribute his own suggestions to the general fund of information.

About a year ago it was decided to open a department in the Scientific American devoted to the interests of the handy man. There was an almost immediate response. Hundreds of valuable suggestions poured in from every part of this country and from abroad as well. Not only amateur mechanics, but professional men as well were eager to recount their experiences in emergencies and offer useful bits of information, ingenious ideas, wrinkles or "kinks," as they are called. Aside from these, many valuable contributions came from men in other walks of life—resourceful men, who showed their aptness at doing things about the house, in the garden, on the farm. The electrician and the man in the physics and chemical laboratory furnished another tributary to the flood of ideas. Automobiles, motor cycles, motor boats and the like frequently call for a display of ingenuity among a class of men who otherwise would never touch a tool. These also contributed a large share of suggestions that poured in upon us. It was apparent from the outset that the Handy Man's Workshop Department in the Scientific American would be utterly inadequate for so large a volume of material, but rather than reject any really useful ideas for lack of space we have collected the worthier suggestions, which we present in the present volume. They have all been classified and arranged in eight chapters, under the following headings:

I, Fitting up a Workshop; II, Shop Kinks; III, Soldering of Metals; IV, The Handy Man in the Factory; V, The Handy Man's Experimental Laboratory; VI, The Handy Man's Electrical Laboratory; VII, The Handy Man About the House; VIII, The Handy Sportsman; IX, Model Toy Flying Machines. Index.

Concrete Pottery and Garden Furniture

By RALPH C. DAVISON

Assistant Secretary Concrete Association of America

12mo. 196 Pages. 140 Illustrations.
Price $1.50 postpaid.

THIS work should appeal strongly to all those interested in ornamental concrete, as the author has taken up and explained in detail in a most practical manner the various methods of casting concrete in ornamental shapes. The titles of the thirteen chapters which this book contains will give a general idea of the broad character of the work. They are entitled:

I, Making Wire Forms and Frames; II, Covering the Wire Frames and Modeling the Cement Mortar into Form; III, Plaster Molds for Simple Forms; IV, Plaster Molds for Objects Having Carved Outlines; V, Combination of Casting and Modeling—An Egyptian Vase; VI, Glue Molds; VII, Colored Concrete and Methods Used for Producing Designs with Same; VIII, Selection of Aggregates; IX, Wooden Molds—Ornamental Flower Pots Modeled by Hand and Inlaid With Colored Tile; X, Concrete Pedestals; XI, Concrete Benches; XII, Concrete Fences; XIII, Miscellaneous, Including Tools, Waterproofing, and Reinforcing.

The first two chapters explain a most unique and original method of working pottery which has been developed by the author. The chapter on color work alone is worth many times the cost of the book inasmuch as there is little known on this subject, and there is a large and growing demand for this class of work. The author has taken for granted that the reader knows nothing whatever about the material and has explained each progressive step in the various operations throughout in detail. These directions have been supplemented with half-tones and line illustrations which are so clear that no one can misunderstand them. The amateur craftsman who has been working in clay will especially appreciate the adaptability of concrete for pottery work, inasmuch as it is a cold process throughout, thus doing away with the necessity of kiln firing, which is necessary with the former material. The book is well gotten up, and is printed on heavy glazed paper and [illegible] by [illegible] illustrations throughout, which clearly show the unlimited possibilities of ornamentation in concrete.

The Middle West Number of the SCIENTIFIC AMERICAN

On December 11th, 1909, the Scientific American will issue a number devoted entirely to the wonderful Middle West region of the United States, a number which will set forth broadly and lucidly not only the agricultural interests of that region, but also those larger engineering undertakings which are destined to transform the Middle West in part at least, into a manufacturing territory

With that object in view the Middle West Number will publish articles on the following subjects

I. The Chicago and Gulf Waterway - An illustrated description of Chicago's drainage canal, an engineering work which stands without a parallel in the world.

II Chicago as a Railroad Center. Chicago is the greatest railroad center in the world.

III. The Wonderful Grain Trade of Chicago. —Chicago is an enormous wheat bin, into which much of the grain raised in the middle West is poured.

IV. Shipping on the Great Lakes.—Most of the iron ore that is now smelted in Pennsylvania is mined in the middle West. To transport it to the blast furnaces of the East at a cost which will enable American steel makers to compete with foreign steel makers, it has been necessary to devise a new kind of lake transportation. Ships of [illegible] and [illegible] tons burden have been constructed which convey ore at small cost through the Great Lakes, and which are without a counterpart anywhere in the world.

V. The Handling and Shipment of Iron Ore.—The above-mentioned fact that iron ore is mined in the middle West and smelted in the East has necessitated not only the construction of special freight-carrying steamers, but also the designing of special machinery for loading and unloading the ore from the steamers.

VI. Freighting on the Mississippi —Freighting on the Mississippi is a more important industry than most of us may realize.

VII. The Steel Industry One of the greatest steel plants in the world is that which has been built at Gary

VIII. The Freight Subway System of Chicago. Chicago can boast of a rational system of handling freight by means of subways.

IX. The Water Supply of Chicago. —Chicago's source of water is Lake Michigan. The city is supplied with water by means of a tunnel which extends two miles out into the lake.

X Reclaiming Arid Lands. The United States Government has under way many irrigation projects for the purpose of reclaiming lands which are arid but which will blossom if properly watered

XI Harvesting the Grain of the Middle West Farms that cover not acres but square miles, crops that aggregate not simply bushels but car loads, have rendered it necessary to plant and harvest on an unprecedented scale in the middle West. The ingenious agricultural machinery which has been designed to cope with these peculiar conditions is described and illustrated

The Middle West Number will be more than twice the size of the regular SCIENTIFIC AMERICAN It will be lavishly illustrated It will be contained in a colored cover which strikingly depicts Chicago's grain elevators at work. Order from your newsdealer or from

MUNN & COMPANY, Inc., 361 Broadway, New York City

with the distance to which the cylinders are moved back beyond the tube ends This distance is marked by a scale upon which is read the point where the subject first perceives the perfume, and thus is the acuteness of each nostril determined

Taste is measured by solutions of sugar, quinine, tartaric acid, salt, etc, which are more and more diluted with water until the tongue—to which they are applied with a dropper—no longer perceives the flavors, and the weakness of the solution marks the acuteness of the subject's sense of taste

When testing for acuteness of touch, the examiner holds what appears to be a rimless wheel from whose hub radiate a score of slender spokes From the free end of each hangs a thread of slenderest cocoon fiber suspending a small disk of elder pith All of the disks are of equal size and apparently of equal weight, but in reality are surmounted by tiny buttons of metal which give them different weights, varying from one to twenty milligrammes (1/65 to 20/65 of a grain) The subject being blindfolded, the examiner, commencing with the lightest disk, successively lowers one at a time upon the subject's skin Several of the lighter disks are not felt, but soon there is applied one that is and the weight of this lightest disk perceived determines the subject's sensitiveness. There are additional devices for measuring the various other elements of feeling, such as perceptions of weight, temperature, pressure, pain, etc.

◆

INDOOR BED TENTS.

(*Concluded from page 416.*)

in the room, and two persons can sleep in the same bed, while only one uses the tent.

This, so far, has been a most successful device for admitting fresh air on sanitary principles to a sleeping room It enables one to breathe the outside air without danger of being chilled or exposed to drafts and colds. Some who tried this tent felt that the fresh air was too cold in storms or wet weather, and they use an outside awning, which can be adjusted at pleasure With these tents the body can be kept warm, while the head, which is toughened to the cold can obtain the stimulation it needs This last can be modified by a Canton flannel hood, which can be made so it will come down over the shoulders, and have a face opening large enough to leave the eyes, mouth, and nose exposed. The cape of this hood covers the shoulders if by any accident the bed clothes slip off them

Fresh air allays sweating, provides good sleep—these tents are capital for insomnia—and helps the appetite The cold air increases resistance to disease purifies the blood and prevents consumption, three reasons why one should breathe it at night The theory of keeping the head in the cold and the body warm is that the body loses eighty to ninety per cent of its heat through the skin by radiation, and cold is bracing only when it comes in contact with the respiratory organs On this theory no good results are obtained when the feet and lower limbs get cold On a cold night one can move away at least twelve inches from the window and still be under the tent, get perfect circulation, and be sure of getting up in a warm room in the morning

Not so many years ago Americans as well as foreigners were afraid of the night air, though we have no such malarial districts as around Rome. Fortunately, we are learning to know better, and workers in Little Italy and the slums where foreigners congregate in cities are pushing the fresh air movement with all their might Fresh air and plenty of it is the best preventive for consumption the grip, bronchitis, common colds and pneumonia. Some sort of inside window tent and paper napkins tissue paper or pieces of gauze which are now used by some people for handkerchiefs are destined to go a long way toward keeping people well warding off disease and the "Great White Plague "

$2.40 Per 100 Instead of $5.00

AND THIS HANDY CIGAR-CUTTER FREE for XMAS

Morton R. Edwin Panatela

is by all standards of comparison a 10c. cigar. It will satisfy the most cranky smoker of imported brands. It is fully 5⅛ inches long, strictly hand-made, of choicest Havana tobacco—genuine Sumatra Wrapper. It smokes freely and evenly—never chars down the side, but keeps burning coolly and fragrantly to the last toothhold.

Actual Size

The reason this cigar is sold at $2 40 instead of $5 00 per hundred is because I buy and sell for cash. I ask no credit, neither do I give it. I personally buy my tobacco direct from the grower in Cuba, and pay him at least five weeks before the tobacco reaches the U S Custom House. I buy *for less* and sell *for less*. The man who buys and sells on credit cannot compete with me.

I want you to be on "Smoking terms" with my Panatelas, because you'll buy them again and again—that's why I am willing to send you a clever patented cigar cutter free with your first order. This cigar cutter retails at 50c.

Send me $2 40 for 100 Morton R Edwin Panatelas. Smoke as many as you like—smoke them all if you want to and if you then tell me that you didn't receive more than you expected, I'll return your money and we'll remain friends.

If you want to know who I am and whether or not I run my business on the square, if you have any doubts as to my making good if my cigars don't, just inquire from any bank or commercial agency about me. If you don't like the report you get, keep your cash at home.

Illustrated Price List sent on request

A Little Book About Fort Smith

Send to-day for it and find out about the opportunities offered in the most rapidly growing city between St Louis and Dallas.

Did you see our advertisement "WE WANT FACTORIES"?

We want more now

Fort Smith, Arkansas, offers to capital seeking investment in factories and to individuals or corporations having manufacturing plants and looking for new locations the best proposition possible to-day in the United States

Fort Smith is situated in the center of almost fabulously undeveloped wealth of semi-anthracite coal, the largest gas field in the United States, vast deposits of building stone, and in the close neighborhood of approximately twenty billion feet of commercial hard and soft wood timber

Fort Smith has forty thousand population—nine railways—and is the natural and logical center for the manufacturing and wholesale market for the Southwest.

Fort Smith has splendid homes, fine schools and churches, beautiful parks and public buildings, and every street in the city is being paved. It presents magnificent opportunities for both labor and capital. Jobbing trade now $40 000,000 annually

We want factories of every kind and character, and will make every reasonable concession to parties desiring to locate here

For further information address the COMMERCIAL LEAGUE, Fort Smith, Arkansas

The Editor is always glad to receive for examination illustrated articles on subjects of timely interest. If the photographs are *sharp*, the articles *short*, and the facts *authentic*, the contributions will receive special attention. Accepted articles will be paid for at regular space rates

AGRICULTURE THE BASIS OF PROSPERITY

If any doubt existed that agriculture is the true basis of the prosperity of the United States it must surely give way before the astounding array of figures presented by the Secretary of Agriculture in his Thirteenth Annual Report which has reached this office as we go to press with the Middle West Number Figures of statistics that reach into the billions become at least to the average mind merely symbolical but when the Secretary tells us that for the present year the value of farm products in the United States is $8 760 000 000 and that it represents a gain of $869 000 000 over the year preceding we can understand why it is that not even our vast manufacturing activity, expressed in great steel mills machine shops and factories innumerable, can compare in the value of its output with the products of the farm

Elsewhere in the present issue we have shown how greatly our industrial prosperity has been due to the invention of labor-saving machinery Particularly potent has been this influence during the past decade during which there has been an increasing appreciation of and demand for the latest and most improved appliances Formerly the scarcity of hired labor discouraged the farmer in the endeavor to get out of his land the full measure of its productive capacity Thanks to mechanical appliances the output for a given amount of hired help has been trebled and in certain classes of work has been multiplied tenfold

To our excellent State agricultural colleges furthermore and the various educational institutions devoted to agriculture to say nothing of the work of the Bureau of Agriculture is due much of the credit for the present prosperity The farmer of to-day is getting a larger return from the land because of his more intimate knowledge of the character of the soil the nature of the crops for which that soil is adapted and the proper times seasons and methods of plowing seed time and harvest

These influences coupled with the rapid increase in the acreage of cultivated land and the breaking up of the old ranges and huge wheat farms into smaller holdings on which intensive cultivation is carried on have served during the past eleven years to just about double the annual value of farm products, the increase being from $4 417 000 000 to $8 760 000 000 The total value for these eleven years reaches the enormous sum of seventy billion dollars Little wonder is it that in some of the great corn and wheat producing States of the Middle West the farmers are enjoying a period of unparalleled prosperity This princely sum has served to sweep away the farm mortgage—that nightmare of the struggling husbandman of fifteen or twenty years ago It has established banks has replaced the tumbledown homestead with modern homes filled with the latest conveniences of civilization by telegraph telephone and railroad it has brought the farmer into intimate touch with the outside world, making him in no mean sense cosmopolitan and it has served to render doubly secure the traditional right of the farmer to be considered as the backbone of the nation in its larger financial and political interests

In looking through the details of this report we find that the corn crop takes the lead in value with a total of $1 720 000 000 and this the Secretary tells us nearly equals the value of the clothing and personal adornments of the [illegible] 000 000 people enumerated by the census of 1900 Equal in value to the gold and silver coin and bullion of the United States "it has grown up from the soil and out of the air in 120 days $15 000 000 a day for one crop" Second in value is the cotton crop the lint and seed of which are worth about $850 000 000 to the farmer Then follows wheat whose crop this year is worth about $725 000 000 at the farm The hay crop represents 665 million dollars, oats, 400 million dollars, potatoes, 212 million dollars, and tobacco, nearly 100 million dollars.

In conclusion, it should be noted that the increase of $869 000,000 in the value of farm products this year over 1908 is sufficient to buy a new equipment of farm machinery for over six million farms and that the value of the cereal crops of the farmer would pay for all the machinery, tools, and implements of the entire manufacturing industry Finally the Secretary tells us that the value of all crops of $5,700 000 000 would make a half payment on the value of all steam railroads according to the valuations of 1904

The pertinence of these statistics to an issue devoted to the Middle West will be appreciated when it is borne in mind that the Middle or Central West contains more than one-half of the wealth invested in improved farms in the United States that it has more than one-half of the live stock and neat cattle that it produces nearly 80 per cent of the food products and more than one-half of the cereals that are grown in the entire country

SEA STRENGTH OF PRINCIPAL NAVAL POWERS.

Toward the close of each year our Navy Department through its Office of Naval Intelligence issues a comparative table showing the warship tonnage of the principal naval powers It is based on the number and displacement of warships built and building of 1 000 or more tons and of torpedo craft of more than 50 tons The statement for the present year, which shows the relative standing of the navies on November 1st possesses special interest because it gives an authoritative statement as to the present strength of the navies in ships of the "Dreadnought" type—a subject regarding which the public has been treated during the past few months to overmuch literature of a sensational and misleading character

Of battleships of the "Dreadnought" type, Great Britain has afloat and completed four Germany two, and the United States two France Japan, Russia, Italy and Austria have not as yet completed a ship of the Dreadnought type Of Dreadnoughts under construction Great Britain possesses seven, Germany six the United States four, Japan two, Russia four, and Italy one France and Austria have no Dreadnoughts under construction In this connection it should be mentioned that our Navy Department does not consider that a battleship is entitled to be reckoned as of the "Dreadnought" type unless her main battery consists entirely of guns 11 inches or more in caliber This eliminates the six French battleships of the "Danton" type carrying four 12s and twelve 9 4s and the three Austrian battleships of the "Ferdinand" type carrying four 12s and eight 9 4s

Of armored cruisers of the "Invincible" type, Great Britain possesses three and has two under construction, Germany has none completed and three under construction and Japan has one completed and one building Adding together the totals for ships armed entirely with big guns both Dreadnoughts and Invincibles we find that Great Britain has seven completed of 125 450 tons displacement and nine under construction of 191 000 tons Germany has two completed of 36 000 tons and nine under construction of 183 000 tons the United States has two completed of 32 000 tons and four under construction of 83 460 tons, Japan has built one of 14 600 tons and is building three of 56 200 tons total displacement, Russia has none completed and is building four of 92,000 tons total displacement, Italy has none completed, and one of 18 600 tons under construction France and Austria have nothing either afloat or on the stocks of the all big gun type

Of battleships of the first class other than "Dreadnoughts" (in which enumeration the Navy Department includes all battleships of about 10,000 tons displacement or over that are less than twenty years old unless they have been reconstructed and re-armed since 1900) Great Britain possesses forty nine of 714,750 tons displacement, Germany twenty four of 282 424 tons the United States twenty five of 334,146 tons, France, seventeen of 215 270 tons, Japan, twelve of 171 898 tons, Russia five of 166,000 tons, Italy ten of 123 600 tons and Austria, three of 31 800 tons Great Britain Germany, the United States and Italy are building no battleships of this class, but France has six, Japan one Russia four, and Austria three under construction

Of armored cruisers other than the "Invincible" type Great Britain possesses thirty five of 416,600 tons displacement, Germany, nine of 86,693 tons, the United States, twelve of 157 445 tons France, twenty one of 192 982 tons, Japan, eleven of 180,900 tons, Russia seven of 70 200 tons, Italy eight of 59 000 tons, and Austria, three of 18 800 tons

In the class of torpedo-boat destroyers, Great Britain leads with 148, followed by Russia with 97, Germany with 79, Japan with 56 France with 56 the United States with 17 Italy with 17 and Austria with 6 Great Britain has 20 torpedo boat destroyers under construction, the United States 19, Germany 12, France 16 Japan 3 and Austria 6

The following table gives the [illegible] warship tonnage both at present and [illegible] now under construction are [illegible] noted that the only change in rel[illegible] is the second list is that Germany will [illegible] second position at present held by the Unit[illegible].

RELATIVE ORDER OF WARS[illegible]

Nation.	At Present, Tonnage.	With All Vessels Completed, Tonnage.
Great Britain	1,[illegible]50	2,005,[illegible]73
United States	[illegible]	785,[illegible]7
Germany	60[illegible]	[illegible]0,692
France	66[illegible]	766,906
Japan	396,[illegible]	489,704
Russia	259,[illegible]	412,350
Italy	216,0[illegible]	257,818
Austria	114,597	167,[illegible]7

Referring to the statistics of total displacement, particularly of battleships of the pre-"Dreadnought" type, we wish to draw attention to the fact that although Germany possesses only one battleship less than the United States, the average displacement of the German ships is very much smaller, being about 11,770 tons as against 13,370 for the United States battleships Furthermore, our strength in this class of vessel is incomparably stronger, since every one of these twenty five ships carries a main battery of four guns of 12 or 13 inch caliber whereas ten of the German battleships carry nothing heavier than a 9 4 inch gun, a weapon which at the great ranges of 7,000 to 9,000 yards at which modern battles will be fought would be altogether ineffective against battleship armor Hence, as late as a year ago when Germany had no "Dreadnoughts" afloat, she actually possessed only fourteen battleships capable of fighting effectively at modern ranges, as against twenty five flying the United States flag, and forty nine under that of Great Britain.

It is here that the careful observer of naval development must look for an explanation of the feverish haste with which Germany is building a fleet of "Dreadnoughts" The short-sighted policy which led to the mounting of the 9 4 inch gun as the principal arm in her first two squadrons of battleships, left her navy in a very serious condition when the absolute superiority of the 12 inch gun was demonstrated in the battle of the Sea of Japan Her present lavish expenditure on battleships must be regarded rather in the light of an effort to retrieve a disastrous error than as a distinct challenge to the supremacy of the British or any other navy

Nor is it any answer to this view of the case to state, as has so often been done of late, that the construction of the first "Dreadnought" robbed all existing battleships of their right to be named as such We confidently predict that the battleships of the older class will play an unexpectedly important *rôle* in the next great war and when two theoretically unsinkable fleets of "Dreadnoughts" have hammered each other into a state of comparative exhaustion, it will be the nation that can send in the most numerous second line of older ships armed with a mixed battery of 12s and smaller rapid fire pieces, that will win the day

THE SECOND REFRIGERATION CONGRESS.

The Second International Congress of Refrigeration will convene in Vienna Austria, from September 29th to October 3d 1910 If anything like the interest displayed at the first congress is experienced the meeting will be a tremendous success.

At the first international congress which was held in Paris France October 1908 out of a total membership of more than 6,000 about 2 000 were in actual attendance from all parts of the world About thirty delegates went from America (out of a membership of 401) representing the principal cold-storage houses, manufacturers of ice-making machines, and other allied industries The first congress was a complete success, and has been the means of arousing the highest interest in the work of refrigeration Since it was held, national associations of refrigeration have been formed in many different countries, including the United States, Great Britain, Germany, Austria, France, etc where the preservation of perishable products is being investigated and studied with great care There is every reason to expect substantial results of a practical character The second congress, to be held in Vienna in 1910, is being organized very systematically, having the advantage of the experience of the first congress, and it is safe to say that the second congress will make still more valuable additions to our knowledge on the subject involved.

These matters are of the greatest importance to a large and growing industry, particularly in the United States involving as they do the encouragement of growers and producers of perishable products.

According to the Geological Survey, the United States leads all other countries in the conversion of raw asbestos into manufactured products, although much less than 1 per cent of the material used is mined in this country

ENGINEERING.

[illegible] another subway in Brooklyn are being con[illegible] Public Service Commission If adopted, they will be an extension of the Brooklyn part of the bridge loop through the Eastern Parkway and Brownsville sections.

The efforts of the Chilian engineer, Señor Unduraga, for a canal project which had as its object the construction of a rival system to the Panama Canal, have been abandoned The canal was to extend from the Gulf of Darien along the Altrato River and its branches across Colombia to the Pacific German and British capitalists have expressed their willingness to build a canal which cannot be closed in case of war, the Colombian government, however, would not agree to give a concession, owing to the fear of possible reprisals on the part of the United States.

The new steamers "Olympic" and "Titanic" will be equipped with glass screens on the promenade decks, so that an unobstructed view seaward can be obtained by the passengers in all weathers. Passengers suffer much discomfort by the heavy canvas screens which are strung into place when rain or spray drives on board The new glass screens will not interfere with the view of the boisterous sea, and will also do away with the stuffy feeling engendered by the canvas. The "Rotterdam" is thus equipped, and the novelty has met with much favor The windows are of heavy plate glass, carefully balanced, and slide up or down in the steel fittings which complete the seaward side.

The War Department of the United States has been strongly fortifying the islands at the mouth of Manila Bay On El Fraile Island a fixed battleship of concrete having two steel turrets has been erected, in each of which turrets are mounted two 14 inch guns which can be trained in any direction by the gun crew inside The guns are operated by the general fire-control station on Corregidor Island, where the principal fortifications of the mouth of the bay are located These fortifications are practically complete, and include six 12-inch, one 10-inch, four 6-inch and four 3 inch guns. There are also twelve 12-inch mortars and sufficient equipment for mining the two channels to Manila Bay The artificial ship referred to will be about 100 feet wide and 1,200 feet long

One hundred and fifty locomotives of the Lehigh Valley Railroad are being equipped with a new fuel saving device On all locomotives the air-brake pumps are operated by steam, and it has been the practice to conduct the exhaust steam from the pumps to the smokebox to which the stack is attached and then to release it, causing a draft Considerable work is done by the brake pumps when the locomotive is at a stand still, thus causing a needless loss of fuel By the new arrangement, the exhaust steam is carried outside instead of inside the smokestack. Tests made by the above-named railroad show that the company is saving about 1 000 pounds of coal per locomotive on the descent of the grade from Glen Summit to Penn Haven Junction Penn , a distance of twenty-six miles.

Heavy explosions in the sewers of a portion of New York city containing many garages, states a contemporary, again draw attention to the danger of allowing petrol to enter sewers Some of these explosions were so violent as to resemble the explosion of a small boiler Manhole covers were blown into the air, windows in the neighborhood were shattered, and a number of persons injured. The sewers of the city discharge into tide water, and at high tide the sewage in them backs up in some cases. It is probable that petrol floated on the surface of the sewage when the latter was backed up by high tide, and its vapor was ignited by a spark that might have been due to several causes. While such explosions will not follow every discharge of petrol into sewers, their occasional occurrence and the possibility of much serious injury from them, states our contemporary, are a justification for rigid rules efficiently enforced to prevent the practice

A new device for the prevention of train collisions was recently tested on the Erie tracks between Newark and Nutley, N J The device is an electric one, and is intended to obviate head-on collisions. When the fast-approaching trains equipped with the new device get within half a mile of each other, the air brakes are set automatically, not with the usual suddenness in an emergency, but with a gradually increasing force, the same as a skillful engineer would employ in bringing his train to a halt at a station The trains stopped far enough away from each other to avoid mishap, and all this happened without either engineer moving a hand toward the throttle lever or air brake, the device working automatically. The invention is operated by a third rail, the shoe from the locomotive touching the rail and receiving power through it both for the operation of the emergency brake and also for a telephone. The principle is similar to that of the block-signal system, the track being divided into zones. The brakes can be applied sharply or their operation may be graduated, so that trains may be slowly brought to a standstill.

ELECTRICAL.

Electrical exhibitions seem to be growing in favor with manufacturers, and also receive hearty support from the general public. Only the other day Boston had its first electrical show, and now we learn that San Francisco is to have one from January 29th to February 5th, and Philadelphia during the week beginning February 14th, 1910

A firm in Germany that is building a storage battery locomotive has adopted the Edison storage battery because of its efficiency and lightness. A small locomotive about 25 feet in length has been built It is equipped with two series motors of 35 horse-power each, which are geared to the axles The locomotive weighs 19½ tons, including the battery, which weighs 5 9 tons. At a recent test the locomotive traveled 130 miles on a single charge drawing a car weighing 33 tons.

The city of Ashtabula Ohio, is being fitted with a new telephone equipment which is called 'automanual,' for the reason that it is largely automatic though it requires some manual control The telephone operator is provided with three sets of keys, one of which is operated to connect her receiver with the calling line and as soon as she receives the number she presses keys corresponding to this number and then operates a starting key which automatically connects the calling line with the desired subscriber This done the two circuits are disconnected from all other lines and from the operator so that the conversation cannot be overheard or interrupted by anyone

The German Agricultural Department has been developing the peat lands between Aurich and Wilhelmshaven A canal has been dredged through them, with small branch canals to drain out the bog It was found necessary to operate the machinery used for this purpose with electricity because the vibration of steam engines caused earth slips Accordingly an electric power station was established The quantity of peat obtained from these lands was so large that it was difficult to find a market for it all without doing injury to the smaller peat bog owners Consequently the peat was used in the power station for fuel, and the power output was increased so as to supply distant centers as well as the immediate neighborhood with current

Steam turbines are not the best prime movers for driving propeller shafts, because they are not sufficiently flexible and their greatest efficiency is obtained only when they are operating at speeds that are too high for the propellers For this reason efforts have been made to introduce an efficient transmission gear between the turbine and the propeller shaft At a recent meeting of the Society of Naval Architects and Marine Engineers, held in this city, a paper was read by Mr W L R Emmet on this subject proposing the use of a combination electric drive While the general idea is not new, Mr Emmet presents some novel details Twin screws would be used each driven by an electric motor and a low pressure turbine the motor being energized by a generator connected to a high pressure turbine The low pressure turbine would deliver three-fifths of the power when traveling at full speed, and at low speed would carry no load whatever A proposition has been made to the government to equip one of the new battleships with this system

A number of questions on electrolysis were submitted by the chairman of the Electrolysis Committee in Chicago to the United States Bureau of Manufactures for investigation by American consuls in ten of the largest European cities. The questions were as follows 1 The use of the track rails for the electric return circuit of street railway lines. 2 The permissible drop in potential over the return circuits of street railway lines. 3 The maximum difference in potential between track rails used as return circuits and gas pipes water pipes, or other metallic structures contiguous to the track 4 Regulations or practices with reference to electrically connecting track rails to gas mains, water pipes or other metallic sub-structures. A summary of the answers of the consuls in the cities referred to has just been published in the *Daily Consular and Trade Reports* In all of the cities rails are used for the return circuit The permissible drop in potential over street railway return circuits in London is 7 volts maximum in Paris 1 volt per kilometer, 5 volts maximum, in Vienna, 5 to 7 volts, St. Petersburg and Moscow 1 5 volts in the city and 3 volts in the suburbs Glasgow and Liverpool, 7 volts, and Christiania 10 volts. The potential difference between track rails and contiguous pipes for London was pipes +1 4 volts and pipes —4 2 volts, Paris, average of 1 volt, Vienna maximum observed 1 volt; Glasgow observed less than 1 volt, Liverpool maximum, 4 5 volts, Christiania maximum, about 5 volts. In London and Glasgow electrical connections between negative returns and contiguous pipes are permitted The cities of Berlin and Brussels make no specific regulations regarding any of the last three questions.

SCIENCE.

Prof. Hergesell of the Strasburg University is bound for St Thomas, West Indies to make atmospheric observations on the Atlantic as part of an international study undertaken by the great meteorological observatories of the world

A German chemist has found 145 grains of free organic bases, estimated as nicotine and 10 grains of combined organic bases, estimated as nicotine, in the smoke from 300 cigars Hence of the entire quantity of organic bases which is contained in tobacco smoke, 93 per cent are present in the free state

French colonial authorities have inaugurated a serious attempt to introduce in the French market the zebu of Madagascar as a substitute for beef The first batch of a dozen carcasses sold in the Paris stalls brought the prices of the highest grades of cattle Herds of zebus otherwise known as Indian oxen which have been threatened with extermination are now being rapidly restored and probably 1 500 000 head roam the plateaus of Madagascar The meat of the zebu is said to be savory and nutritious and is equal to beef

Some fabrics can easily be made waterproof by soaking them in a solution of celluloid in acetone ether amyl acetate, or other volatile solvent The evaporation of the solvent leaves the fabric coated with a thin film of celluloid which is firmly united with the fiber The thickness of the film can be increased by repeating the operation or by using a stronger solution Fabrics thus treated are absolutely waterproof and can be washed without absorbing water Linen which is first starched and then treated by this process can be washed with soap and water without removing the starch

Plans for a national Audubon university on the University Settlement plan, to be endowed with $1 000 000 have been announced in this city Based on the known annual crop loss of $1 000 000 000 due to the spreading pests that the insect-eating birds destroy the calculations of the National Association of Audubon Societies which is back of this project show that the teaching of bird value from such an institution must result in wiping out at least one per cent of the huge national penalty for popular lack of knowledge on this subject For every hundred thousand dollars put into this work of economic education a million is sure to be saved to the agricultural interests of the whole people Successful agriculture means general prosperity and thus every merchant manufacturer and business man of any sort is vitally interested and should bear his part in the plan to educate the public in the great economic principles of bird conservation

The manioc root contains from two to three hundredths of one per cent of hydrocyanic or prussic acid which is so poisonous that even this small proportion may produce serious results if it is not thoroughly removed by washing in the preparation of tapioca semolina and other food products which are obtained from the manioc The presence of prussic acid in these products has been detected by analysis The same statement is true of the coarser products employed in brewing distilling, and cattle feeding some of which have been found to contain a quantity of hydrocyanic acid equivalent to a dose of more than half a grain Troy in the daily ration of an animal Thorough cooking volatilizes the hydrocyanic acid already present and destroys the diastases which convert certain saccharine ingredients into cyanogen compounds as has been proved in the case of Javanese and Burmese beans which also contain hydrocyanic acid but manioc products are often fed raw They should always be thoroughly cooked and should be analyzed if the slightest ill effect follows their use

Mr C P Butler, astronomer at the Observatory of Solar Physics has just presented to the Royal Photographic Society of London some very curious photographs of the spectra of Jupiter Saturn Uranus and Neptune taken by the American astronomer Percival Lowell at the Flagstaff Observatory There are in fact in these spectra absorption bands which coincide with the rays of chlorophyl which is as everyone knows the green coloring matter of vegetable cells Thus one would be led to believe from these results that these planets might be covered with some sort of vegetation colored with chlorophyl Remark worthy of attention The lines corresponding with the absorption bands of chlorophyl are more intense as the planet is farther from the sun so that it is on Neptune that plants would be met with in greatest numbers and would be most vividly colored with green But again it would have to be admitted that these planets were all covered with luxuriant vegetation at the moment when the photographs were taken which seems all the more improbable because everything leads us to believe that Jupiter and Saturn are worlds far from being completed However these results are very interesting although contradicting the opinions generally received and they deserve to be noted while awaiting another explanation.

The Reclamation of the Arid Lands of the West.

Of all the public works undertaken by the United States government there is probably none that is more popular than the noble scheme for the reclamation of the arid and semi arid lands of the West The story of the construction of huge artificial reservoirs far reaching canals and costly tunnels for the storage of the flood waters and their conveyance to barren lands which await only the magic touch of the irrigation ditch to develop their wonderful fertility is one of fascinating interest and the progress of the work has been made thoroughly familiar to the people of the United States by the brush and camera of the artist and the ever ready pen of the descriptive writer

We must not make the mistake however of supposing that the history of irrigation in the United States dates from the year 1902, when the [illegible] decided to apply its vast resources to the [illegible] its beginning we must go back to the re[illegible] unwritten past, even to the romantic age of the cliff dwellers, for there is clear evidence that in the valleys of New Mexico there once existed a complete system of irrigation canals, that served to render these now desolate districts both fertile and populous For reasons which we do not know and probably never shall, these ancient and highly developed races degenerated, their homes fell into decay, and their great engineering works became obliterated Centuries later with the advent of the Spanish settlers irrigation was reintroduced in southern California and in the lower valley of the Rio Grande The mission fathers also by the aid of small dams and canals, rendered

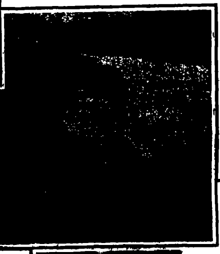
HUNTLEY PROJECT, MONTANA

fruitful certain local areas in California.

The first successful attempt to apply irrigation to the arid regions is to be credited to the Mormons, who in 1847 made their notable settlement on the barren lands of the great interior basin, on the site where now stands Salt Lake City. With the growth of the colony, the work of leading in water from the various outlying streams was extended, and work has been carried on with such good effect that the present extensive system has been pronounced by the Department of Commerce and Labor to be "the most efficient in the country." Many of the pioneers of California turned from mining to irrigated farming, and the work has subsequently been extended to other States, until at the present time over eight million acres of land, which at one time was looked upon as worthless desert, is under cultivation and is producing crops each year whose worth is estimated at over $100,000,000.

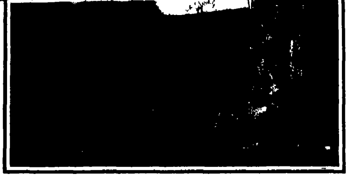
There are four regions of the United States in which irrigation is practised. The arid region, comprising those States and Territories in which agriculture depends almost entirely upon irrigation, the semi arid region, lying midway between the Rocky Mountains and the Mississippi River, where the rainfall is uncertain, the rice-producing States, comprising parts of Texas, Louisiana, the Carolinas, and Georgia, and the humid States, represented by several of the New England, Middle Atlantic, and Gulf States, where there is a limited amount of irrigation. A Government Report of irrigation in the United States in 1902 showed that in the arid States and Territories 8,471,641 acres were under irrigation, in the semi-arid States and Territories, 403,449 acres, in the rice States of the South, 606,199 acres, and 5,788 acres in the humid States, making a total for the whole country of 9,487,077 acres. The number of farms included in these systems were 134,036, and the total cost of the work $93,320,452. Practically the whole of this work has been done by private enterprise. It includes irrigation of every kind from the ambitious scheme of the large corporation down to the individual irrigation ditch of the small farmer. The whole of this work is due to private enterprise unaided by the government.

Concrete flume which carries interstate canal across Spring Canyon.



Footbridge across North Platte River, Pathfinder dam.

This project irrigates 110,000 acres.



Pathfinder dam, 215 feet high, during construction.

THREE VIEWS OF NORTH PLATTE PROJECT, NEBRASKA WYOMING

Naturally private enterprise has attacked the problem in those districts where the physical obstructions were the least and in which the water could be impounded or large rivers tapped and the supply brought to the land to be irrigated with the least possible expenditure of time and money. There still remained vast areas of arid and semi arid land estimated at some thirty million acres in all, which if the necessary engineering skill and large amount of capital could be found for executing the necessary works, might be rendered fruitful and opened up for settlement.

In 1902 the government decided to undertake this great work of reclamation and Congress passed a law providing that the money received from the sale of public lands in the States lying within the arid region be set aside as a reclamation fund to be used in surveys and in the construction and maintenance of irrigation work. A law was passed providing that the reclaimed lands were to be sold in tracts of not less than 40 or more than 160 acres. Under its terms the settlers are to buy their lands direct from

The Wonderful Iron Mines of Lake Superior—How the Ore is Mined and Carried in Bulk.

It usually happens that the attainment by a particular people of great distinction in some special branch of the industrial arts is due to the natural characteristics of the country in which they live This is certainly true of our own country, whose wide extent and rich natural resources have impelled us to the construction of ingenious appliances for the handling and transportation of material in great bulk which have made the name of the American mechanical engineer known throughout the civilized world Particularly is this true with regard to the mining and transportation of minerals, the most bulky and less costly of which (coal and iron ore) are produced and shipped on a scale of magnitude not equaled in any other country of the world

In a Special Number devoted to the Great Middle West, a conspicuous position must necessarily be taken by the steel industry Elsewhere we have dealt with Gary, where the largest and most up-to-date steel works in the world has lately been put in operation The present chapter describes the vast deposits of rich iron ore which lie near the shores of Lake Superior, and those methods of mining, transportation, loading and unloading, by which the enormous bulk of ore which is necessary to keep the blast furnaces of our steel works in continuous operation, is brought from mine to furnace at a cost so low as to enable this country to manufacture steel far more cheaply than any other country in the world

The Lake Superior Iron Mines.—If Nature had set out with the determination to assure for the [illegible] States the premier position in the steel industry of the world, she could scarcely have done so more effectively than by spreading out around the western and southern shores of Lake Superior those huge deposits of iron ore above referred to. Not only do the ore formations cover vast areas, but in the wonderful Mesabi mines the ore lies practically at the surface of the ground, and frequently, after a few feet of overlying material have been stripped off, the cars can be run right into the mine and loaded directly by steam shovels. Furthermore, the Lake Superior ore is of unusual richness, much of it running over sixty per cent iron The principal mines are located in ranges, of which the most famous are the Menominee, Marquette, and Gogebic ranges in Michigan, and the Vermillion and Mesabi ranges in Minnesota. The mines are located from twenty five to seventy-five miles from the shores of Lake Superior Eight separate railroads carry the ore to as many shipping ports on the lake, where it is unloaded into twenty-six docks having a total storage capacity of 1,326 616 tons. The total hauling capacity in a single day

of these eight railroads combined is 250,000 tons. The greatest record for unloading is that of the Duluth, Mesabi & Northern, which in a single day has loaded 165,000 tons into sixteen steamships.

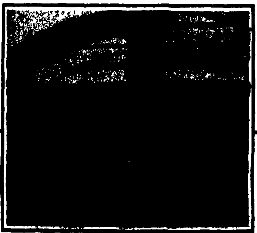
THE "WOLVIN," A TYPICAL LAKE STEAMER FOR THE TRANSPORTATION OF ORE CAPACITY 11,686 TONS

In the course of an interesting and illuminating address dealing with the history of the Lake Superior mines, given last summer by William J Olcott, president of the Oliver Mining Company, Duluth, the speaker drew attention to the fact that in 1844, while William A. Burt was surveying township lines and making geological observations in Marquette County, Michigan, he noticed a deflection of eighty-seven degrees from the normal of the solar compass, and thereupon sought for and found at several points outcrops containing iron ore. In 1847 a forge was started about three miles from these outcrops, and on February 10th, 1848, the first iron to be made in the Lake Superior region was produced by Ariel N Barney, the daily output of the forge being about six tons. The early development of those mines was little more than crude exploration In the winter of 1850, the first ore was hauled to Marquette on the shores of Lake Michigan. In 1852, Congress granted to the State of Michigan 750,000 acres of land for the construction of a small canal around the Rapids of St. Mary's River, connecting Lake Superior and Lake Huron The canal was completed in 1855, and the first shipment of iron ore consisted of 132 tons, which passed through the canal on August 17th of that year In those early days mining was done by open pit work methods the ore being hauled out in carts and dumped into railroad cars The Marquette range furnished all the iron ore from Lake Superior until 1876, when shipments began to be made from Menominee range, from which the total output to date has been 63 641,213 tons In 1885, shipments began to be made from the Gogebic in Michigan and Wisconsin, and from the Vermillion mines in Minnesota. Up to date from Vermillion alone over 28,000,000 tons of high grade ore have been shipped

Ten-ton bucket of unloader in hold of the "Wolvin."



The most famous of the Lake Superior mines, however are those of the great Mesabi range in Minnesota, which extends for an unbroken distance of eighty miles and includes no less than eighty six mines

The geological formation is peculiarly favorable for mining The greater part of the ore bodies lie horizontally and are covered by a shallow bed of glacial drift To get at the ore it is merely necessary to remove the surface covering and then excavate the ore with the steam shovel, loading it directly into the cars trains of which are run into the mines for this purpose Furthermore the ore beds are as rich as they are extensive for analysis shows them to consist of from 47 50 per cent to 61 26 per cent of pure iron, with an average for the whole district of probably about 57 per cent of iron Although the first mine in the Mesabi range was discovered as late as 1890, in the year 1907 over 27 000 000 tons were shipped from this range alone It is the low cost and capacity for enormous production of the Mesabi range says Mr Olcott that is the guarantee of the continued supremacy of the United States in the manufacture of iron and steel '

We are accustomed to look upon the excavation of

The iron ore lies so near the surface that after stripping the glacial surface material a vast horizontal bed of rich ore (60 per cent iron) is exposed. The ore is dug by steam shovels and loaded directly into the cars. Over 1,600,000 tons are shipped out every year

THE RECLAMATION OF THE ARID LANDS OF THE WEST

(Concluded from page 429.)

the government, instead of obtaining them by rent or purchase from land and irrigation companies. The price of the land is determined by the cost of the irrigation works for that particular district, and the funds thus obtained are turned into the general Reclamation Fund and used for the construction of work in other districts. The settlers pay for the land in installments and payment must be completed by the end of ten years. In addition to paying for the land, the farmer is subjected to an annual charge for the water, and the money so received is also applied to the maintenance and improvement of the work. It can thus be seen that the fund is made self perpetuating.

The general surveys for this wonderful work have been made, and the scheme includes some twenty-eight different 'projects,' as they are called, the location of which is indicated on the accompanying map by shaded areas. We also present a table, which gives the area in acres and estimated cost of such part of each project as will be completed by the year 1911. They vary in size from the Salt River project in Arizona, which will bring 210 000 acres under cultivation by the year 1911 at a cost of $6,300,000 down to the Garden City stream in Kansas which will irrigate 8,000 acres at a cost of $350 000. By the close of that year, nearly 2 000 000 acres will have been reclaimed, at a cost of $70 000 000. The works are in various stages of progress. Some are under survey, a few have been only recently commenced, while others are practically completed and are already supplying water to certain sections of the areas served. At the present time over 1,000 000 acres are ready for irrigation, and certain areas which a few years ago formed part of a dry and trackless desert, are now supporting about 21 000 people on farms whose fertility is in many cases truly phenomenal. A large number of towns have sprung up, and the newly-opened districts are being connected by branch lines with the trunk railroads.

The beneficent work of the government does not cease with the turning off the water into the canals. In each district it maintains farmers who are experienced in the local conditions, for the purpose of teaching the newcomers how to till their land suitably to the special conditions and requirements of the districts in which they have settled. Government demonstration farms have been established upon which the fruits and cereals most adapted to the local conditions are raised.

Now it must not for a moment be supposed that the two million acres of land to be brought under irrigation by 1911 represent the whole of the government scheme. As a matter of fact, it marks merely the beginning of a vast system which contemplates the recovery of no less than thirty million acres. These are large figures, let us translate them into the terms of population and taxable value. It is estimated that a fair average value per acre of the irrigated farms, including the value of the land and of the improvements thereon is $150 per acre. If this is a conservative estimate it follows that the total value of the reclaimed land when it has been brought under full cultivation will be $4,500 000 000. Not only will this vast property be added to the total taxable value of the farms of the United States but judging from present conditions, it will provide homes for at least fifteen millions of people, one-half of them living on the farms and the other half in towns and cities. Several of the latter have already been founded in the areas covered by the completed schemes, and are showing every evidence of healthy life and growth. Furthermore the government will possess a valuable asset in the water powers which can be developed by utilizing the great available head of water on many of the projects. By January 1st, 1910, about fifty thousand hydraulic horse-power will be available. This belongs to the government, and will be sold to the settlers for power, light, and other purposes at the cost of production. So valuable is this asset alone, that it will make up the entire cost on some of the projects.

TABLE SHOWING THE TWENTY-EIGHT PROJECTS OF THE RECLAMATION SERVICE

The areas and costs are for such portions of the various projects as will be completed by 1911

Location	Project.	Area in Acres	Estimated Cost.
Arizona	Salt River	210 000	$6,300,000
California	Orland	30,000	1 200,000
California Arizona.	Yuma	100,000	4 500,000
Colorado	Uncompahgre	140,000	5 600,000
Colorado	Grand Valley	50,000	2,250,000
Idaho	Minidoka	160,000	4 000,000
Idaho	Payette-Boise	100,000	8,000,000
Kansas.	Garden City	8,000	350,000
Montana ,	Huntley	30,000	900,000
Montana	Milk River including Saint Mary	30,000	1 200,000
Montana	Sun River	16,000	500,000
Nebraska-Wyoming	North Platte	110,000	5,850,000
Nevada	Truckee Carson.	160,000	4 800,000
New Mexico	Carlsbad	20 000	640,000
New Mexico	Hondo	10,000	370,000
New Mexico	Leasburg	10 000	200,000
New Mexico Texas	Rio Grande	160,000	8,000,000
North Dakota.	Pumping Buford-Trenton Williston	40,000	1 940,000
Montana North Dakota	Lower Yellowstone	65,000	2,700,000
Oregon	Umatilla	18,000	1 100,000
Oregon-California	Klamath	120,000	3,600,000
South Dakota	Belle Fourche	100,000	3,500,000
Utah	Strawberry Valley	30,000	1 500,000
Washington	Okanogan	8,000	500,000
Washington	Sunnyside	40,000	1 400,000
Washington	Tieton	24 000	1,500,000
Washington	Wapato	20,000	600,000
Wyoming	Shoshone.	100,000	4 500,000
		1,910,000	$70,000,000

It is impossible within the limits of the present paper to do more than to give a brief outline of some of the more important of these great works.

YUMA PROJECT CALIFORNIA.—This project consists in the diversion of the waters of the Colorado River by means of the Laguna Dam into two canals, one on each side of the river. The dam is located about ten miles northeast of Yuma, Arizona. These canals will irrigate all the bottom lands of the Colorado and Gila rivers in Arizona between Laguna Dam and the Mexican boundary, about 84,000 acres in all, and in California they will serve 17,000 acres of bottom lands in the Yuma Indian Reservation. This region resembles the fruitful valley of the Nile in its soil, climate, and droughts. The dam, which stretches entirely across the river, is remarkable more for its length than for its height. Unlike the huge Roosevelt, Shoshone, and Pathfinder dams, to be described later, it is an overflow weir, its purpose being to back up the waters of the Colorado sufficiently to provide a full supply for the two irrigating canals. By the year 1911 it will supply water to 100,000 acres at a cost of $4,500,000.

SALT RIVER PROJECT, ARIZONA.—Of an entirely different character are the engineering works of the great Salt River project, by which, within two years from now, 210,000 acres will be irrigated at a cost of $6,300,000. This project involves the construction of a storage dam 284 feet in height, at Roosevelt, Arizona, which will impound 1 284,000 acre feet of water—that is to say, sufficient water to cover that number of acres one foot deep. The dam is most advantageously located in a deep and narrow canyon, whose bottom and sides are of rock. The storage basin of the dam which will have a superficial area of 25.5 square miles, will be large enough to catch and store the waters of the great floods to which the Salt River, in common with most of the rivers of the arid regions, is liable. Because of the remoteness of the work, the construction of the dam has involved heavy incidental engineering expenses. It was necessary to cut a costly road over which to carry in the machinery and supplies, and because of the high price demanded in the bids for the supply of cement, the engineers were driven to the expedient of erecting a cement mill and manufacturing the cement on the spot. The water is released from the dam by massive gates. It flows down the canyon to a point forty miles below the dam where it is diverted into two main canals, one on each side of the river. A power canal 18.5 miles long, serves to develop electric power by which water will be pumped from underground sources, and increase the irrigable area by 50,000 acres, making 210,000 acres in all that will be brought under irrigation by 1911 at a cost of $6,300,000.

SHOSHONE PROJECT, WYOMING.—Near the northern boundary of Wyoming, the government is building another remarkable dam which has the distinction of being the loftiest structure of the kind in the world. It will rise 310 feet above its foundation, and so narrow is the canyon that the masonry will measure only 175 feet along its crest. Here, as at the Roosevelt Dam, it was necessary to cut a road many miles in length out of the solid rock in order to gain access to the site. The dam will create a reservoir with a storage capacity of 456 000 acre-feet, and by 1911 the water will be available on some 100,000 acres of choice land. The dam will regulate the flow of the water, and thirty miles below the dam the stream will be turned into a tunnel three and a quarter miles in length which will conduct it by a large canal into the district to be irrigated.

NORTH PLATTE PROJECT, NEBRASKA WYOMING.—The third of the lofty dams is the structure known as the Pathfinder Dam, so named after the well known explorer, Gen. John C. Fremont, who nearly lost his life at the site of the dam in trying to row through the canyon. Although the structure is about 100 feet less in height than the Pathfinder Dam, the storage basin above it is of such favorable formation that it will impound over 1,000 000 acre-feet, and will be capable of holding in check the greatest of the floods to which the restless North Platte is subject. Below the dam the government has built a great canal, 95 miles in length, which will carry the water to the irrigable lands of Wyoming and Nebraska. The broken character of the ground necessitated the construction of several important concrete viaducts, one of which is shown among our illustrations. Because of the porous nature of the soil the canal for many miles of its length is lined with concrete. By 1911 this system will have brought 110,000 acres under irrigation. When the whole scheme has been developed it will serve some 200,000 acres in Wyoming and an equal amount in Nebraska.

MINIDOKA AND PAYETTE-BOISE PROJECTS, IDAHO.—One of the most important works of the Reclamation Service is that which is being carried out on the Snake River in Idaho. At Minidoka a dam and regulating gate have been built across the river, and 130 miles of canal and 190 miles of ditches will serve to convey the water to 160,000 acres of land. Farther down the river, near the border line between Idaho and Oregon are the Payette-Boise works, which by the end of 1911 will bring 100,000 acres under cultivation. Ultimately, this project will reclaim 372,000 acres of land in the Payette, Boise and Snake rivers in southwestern Idaho.

UNCOMPAHGRE VALLEY PROJECT, COLORADO.—To the public mind the most spectacular of the irrigation works is that known as the Uncompahgre Valley, and this because of the great tunnel through the mountain recently opened by President Taft, which forms the most notable feature of the work. In southwestern Colorado the Uncompahgre and Gunnison rivers flow in approximately parallel courses, 10 miles apart, on either side of a mountain range some two thousand feet in height. The Uncompahgre, which is a comparatively insignificant stream, flows through a valley containing 700,000 acres of rich land, whereas the Gunnison, a much larger river, flows in a deep canyon, where there is practically no land available for cultivation. The United States engineers decided to cut a tunnel, 10½ feet by 12 feet in cross-section, for six miles through the mountain. The location of the tunnel was fixed at a point where the canyon is over half a mile deep. A road sixteen miles long was cut down this gorge, the machinery brought in, power plant established, and a few months ago the tunnel was completed. When President Taft opened the works the waters of the Gunnison River began to flow through the mountain and emerged in a valley, where they will render fertile some 140,000 acres of rich soil.

In conclusion, we should again impress it upon the mind of the reader that the 2 000 000 acres which will be brought under cultivation by the year 1911, represent only about one-fifteenth part of the fertile land which will ultimately be opened for settlement when the various schemes shown on the accompanying map have been worked out to their full development. So judiciously has the matter been handled by the United States Reclamation Service that the work will be self supporting and self perpetuating. So successful has that portion of it which is completed proved to be that it is safe to say the work of reclaiming barren lands in the United States will go on until the whole of the arid lands upon which it is possible and profitable to bring the water have been brought under cultivation.

Limits of space prevent any extended reference to the nature and quantity of the crops that will be produced on these irrigated lands. In many sections the greater part of the acreage will be devoted to the raising of hay and forage, and particularly of alfalfa, for which there is a great demand as winter feed for cattle. The stock, which during the summer is fed upon the high pasture land, in the winter is driven down to the irrigated valley farms, where it feeds directly from the stack. Irrigated land yields about five tons of alfalfa to the acre and its average value is about $5 per ton. As many as 300,000 head of sheep have been fed in this way in one winter on irrigated land near Billings, Montana. The fertility of the farms is something that must be seen to be appreciated. Average land in the East will yield 15 bushels to the acre. On irrigated land in Colorado the yield is 40 bushels. The Eastern farmer may gather in a year one hundred dollars' worth of apples from an acre, whereas on the irrigated land of the West the value of the crop will reach $450 to the acre, and according to Mr. J. C. Blanchard, statistician of the United States Reclamation Service, apple orchards on irrigated land in the Yakima Valley have yielded from $300 to $1,200 per acre annually, while good orchard land sells at from $300 to $2,000 per acre, when containing full-bearing trees. In this same valley the value of farm products in 1907 reached the magnificent sum of $2,625,000, and 65,000 cattle and 20,000 sheep, of a value of $2,000,000, were ranged and fed.

◆

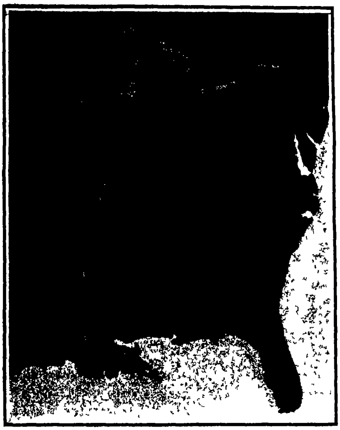
With the purpose of studying enormously high voltages a short experimental transmission line has been built in Sweden which is adapted to operate at 500,000 volts. A special form of transformer is used to furnish this high electro-motive force. Circulating oil is used for insulation between the high and low-tension windings. The line is supported on the suspended type of insulators which are hung at a distance of 11 feet apart. Tests of the surface discharge showed that a wire of 10 square millimeters (0.0155 square inch) cross section would discharge at 35,000 volts, of 20 square millimeters at 50,000 volts, of 100 square millimeters at 200,000 volts, and of 250 square millimeters at 330,000 volts. As the tension was raised to 480,000 volts, the noise grew very loud and sparks leaped from the insulators. At night the glow of the discharge could be seen 2½ miles away.

The Proposed Lakes-to-the-Gulf Deep Waterway.

That portion of the United States which is popularly known as the Middle West, and in the government reports as the North Central Region of the United States, comprises twelve States, whose combined area is 753,550 square miles, and its population approximately thirty millions Within its boundaries are included one-fourth of the area and one-third of the population of the United States

Originally regarded as part of the so-called 'Great American Desert," the Middle West represents to-day more than one-half of the value of the improved farms of the country, contains more than one half of the live stock, produces nearly eighty per cent of the food products and over one-half of the butter, corn, wheat, oats barley rye flaxseed potatoes, and poultry that are raised in the entire United States. Furthermore as a manufacturing center it contains thirty five per cent of the total number of manufacturing establishments, and turns out annually thirty three per cent of the manufactured products of the country Also from the Middle West comes thirty three per cent of the bituminous coal mined in the United States, and seven tenths of the iron ore

The wealth of a country is very closely related to its facilities for transportation, moreover students of the economics of transportation have come to realize that ideal conditions can be reached only when a country is served by a combined system of railroads and canals or other waterways. Of the former the Middle West possesses a veritable network, being served by over 86 000 miles of track, which represents some forty three per cent of the total mileage of the United States This railroad system has been developed along lines that are admirably adapted to meet the conditions, which are, that a huge and bulky tonnage shall be hauled long distances at a low cost Nowhere in the world is freight moved so cheaply as here But when we speak of the railroad system of the Middle West as being admirable, and while every credit is due for the Herculean efforts which have been made to keep pace with the growth of the country, it must be admitted that this vast network of lines, great as it is, has failed to keep pace with the rapid and enormous increase in the products of the farm and the factory Evidence of this is seen in the steadily recurring periods of congestion, when the railroads are quite unable to move the tonnage that is offered with anything like reasonable expedition



BIRD'S EYE VIEW, SHOWING THE VAST AREA OF COUNTRY TO BE SERVED BY THE GULF TO THE LAKES WATERWAY

Nature however has provided the Middle West with a system of natural waterways which awaits only the adjusting hand of the engineer to make it capable of transporting at low cost and with reasonable celerity the more bulky freights of the Middle West, leaving the railroads to deal with the higher class freights, for whose more rapid transportation a greater charge is levied and willingly paid We refer of course to the Mississippi River

This noble river which penetrates the Middle West throughout its entire length from north to south has six hundred tributaries forty five of which are navigable and its drainage area is 1 '67 4[illegible] square miles Its tributaries reach away east and west from the parent stream for a distance of 4 300 miles If one were to set out in a motor boat with the intention of following every one of these affluents from its point of discharge into the Mississippi up to the head of navigation his upstream journeys would aggregate sixteen thousand miles and cause him to traverse twenty three States and Territories

In the early days of the settlement and development of the Mississippi Valley the transportation both of passengers and freight was dependent almost entirely on the river and its tributaries With the advent of the steam railroad and the opening up of what had been known as the Great American Desert lying to the west of the Mississippi and with the construction of a railroad system paralleling the river there was a gradual decline of water borne traffic the passenger travel almost in its entirety and the freight traffic in an ever increasing degree being absorbed by the new and swifter means of transportation

The utility of this great river for the conveyance of freight is greatly curtailed by the fact that it is subject to heavy floods which wash away its banks and deposit the ma

terial in shoals that not only render navigation difficult and hazardous but put a serious limit upon the size and character of the fleet of vessels employed For many decades past the United States government has maintained a low water depth of between eight and nine feet from St Louis to the Gulf This has been done by a system of bank protection dikes and dams assisted by dredging The depth secured however, is so limited as to absolutely prevent the development of the traffic to a point commensurate either with the magnitude of the river, or the agricultural and industrial wealth of the vast empire which Nature destined that it should serve

LOCK WALL; OVERFLOW FOR 40 AND 18-FOOT DAMS, TAIL RACE AND POWER HOUSE.

The recent encouraging revival of interest in the development of our waterways has been nowhere more marked than in the Mississippi Valley Among the various schemes for the improvement of the river the one which overshadows all is the proposal for a deep waterway with a minimum depth of fourteen feet from Lake Michigan at Chicago by way of the Illinois and Mississippi rivers to New Orleans on the Gulf of Mexico The proposal for a waterway from the Lakes to the Gulf dates from the first settlement of the country, and from that time to this several surveys have been made As far back as 1848, the State of Illinois built the Illinois and Michigan Canal, which leaves the Chicago River six miles from the lake, and extends to the head of navigation on the Illinois River at Lasalle a distance of nearly one hundred miles The project included the improvement of the river down to the Mississippi by a system of locks and dams calculated to give a minimum depth from Chicago to St Louis of seven feet.

The Lakes-to-the-Gulf Waterway—The present active agitation for the construction of a fourteen foot waterway from the Lakes to the Gulf originated at the time when the State of Illinois authorized the construction of the Chicago Drainage Canal This great artificial waterway, which, with its connections, is nearly forty miles in length, was constructed for the purpose of preventing contamination of Lake Michigan by the sewage of the city, the whole of which was at that time being discharged into the lake The distance from the mouth of the Chicago River to its junction with the main drainage canal is six miles, and this portion of the channel is to be widened to two hundred feet with a mid-channel depth of twenty-six feet. The main channel is cut from the river through the divide which separates Lake Michigan from the watershed of the Des Plaines and Illinois rivers. It has a uniform depth throughout of twenty two feet, and it varies in bottom width from 110 feet to 202 feet according to the character of the material, earth or rock, through which it is cut. Its length from the Chicago River to the controlling works at Lockport is 28 05 miles. Subsequently to the completion of the canal, a water-power extension was constructed, which added another 4 30

HYDRAULIC DREDGE EXCAVATING CHANNEL

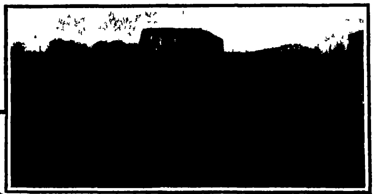
miles of waterway, making a total from Lake Michigan of about 38½ miles Into the drainage canal is admitted from Lake Michigan a volume of water whose flow is equal to 10,000 cubic feet per second

At the end of the canal proper are controlling works consisting of gates and a movable bear trap dam, by which the flow of water from the main channel is controlled, and the height of the water regulated There are seven metal sluice-gates of the Stoney type with a vertical travel of 20 feet and an opening 30 feet wide, and the bear-trap dam has a vertical oscillation of 12 feet on an opening of 160 feet South of the controlling works the Des Plaines River (tributary to the Illinois River) has been widened and deepened to accommodate a flow of 1,500 000 cubic feet of water per minute The main channel, the extension to Joliet, etc, involve a total excavation of over 42,000 000 cubic yards of material, and the estimated cost of the completed work is $50,000,000

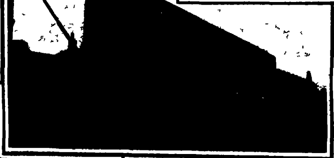
The legislation authorizing the development of the water power passing through the Chicago canal was secured in 1903, the scheme contemplating the extension of the main channel as a waterway and canal for four miles south from the controlling works. The power house, of which we present an illustration, was located on this extension, two miles below the controlling works, at a point where a drop of 34 feet is available for development. The power-house building, which was constructed wholly of concrete, is 70 feet wide, 47 feet high, and 385 feet long

In 1902 Congress provided for a survey by its engineers to determine the feasibility of building a 14-foot waterway from Lockport to Grafton on the Mississippi, near the mouth of the Illinois River, and in 1905 the Board of Engineers submitted a proposal to canalize the river from Lockport to Utica, a distance of 63 5 miles. The plans provide for locks 80 feet wide, 600 feet long and with 42 feet of water over the sills.

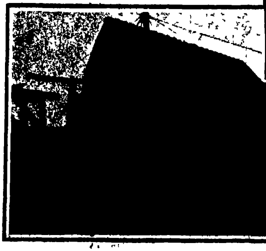
From Utica to Grafton on the Mississippi, 239 5 miles it was proposed to dredge a channel having a bottom width of 200 feet, and depth at low water of 14 feet It is considered that the volume of 10,000 cubic feet, which passes through the Drainage Canal, from Lake Michigan, will supply sufficient water during the summer season to give the required depth of 14 feet from Lockport to the Mississippi River Furthermore it is estimated that the 10,000 cubic feet of water per second will serve for the development of about 135 000 horse-power in that portion of the canal lying between the Drainage Canal and Utica The State of Illinois stands ready to undertake the whole of the work from the end of the Drainage Canal to Grafton, stipulating to turn over the completed navigable channel to the United States on condition that the State retain control of the water power, and that the expense of maintaining the channel be borne by the Federal government.



UPSTREAM FACE BUTTERFLY DAM, CHANNEL EMPTY, DAM CLOSED



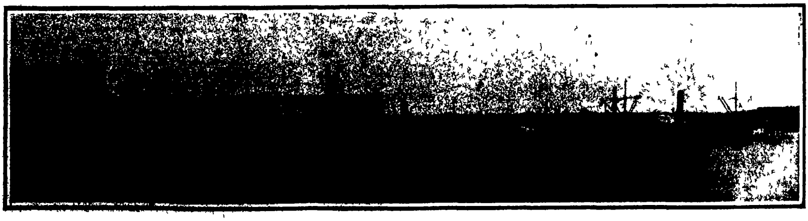
CONSTRUCTION OF STONEY GATES AT CONTROLLING WORKS



FORTY-EIGHT-FOOT SECTOR DAM AT POWER HOUSE.

The problem presented by the 38 miles of the Mississippi River from Grafton to St Louis is complicated by the discharge of the Missouri River which acts as a serious disturbing element, and it was proposed to avoid the difficulty by the construction of an entirely separate waterway along the easterly bank of the river The plan provides for the construction at Alton of a huge wicket dam 2 [illegible]00 feet long which, by raising the water level 14½ feet, would create a pool that would raise the low water level at Alton about 8 feet and in combination with dredging would enable the full 14 feet of depth to be maintained A canal would be cut from the pool just above the easterly end of the dam and extend parallel with the river to the Merchants Bridge at St Louis a distance of [illegible]8 miles The canal would be maintained at the level of the Grafton to Alton pool and at its southerly end a lock 80 feet wide and 600 feet long with a lift of 30 feet would pass the vessels down from the canal to the deep water at St Louis

St Louis to Cairo—The most difficult portion of the whole waterway from the Lakes to the Gulf is the stretch of 180 miles from St Louis to Cairo At low water the river falls on a grade of 0 6 foot per mile producing a rapid current, and there is the added complication that an enormous amount of sediment is brought down from the Missouri River Three methods have been proposed for dealing with this difficult section First, the construction of an independent canal This would be the simplest solution of the problem and the surest but its cost would be altogether prohibitive The second scheme would be to



PANORAMIC VIEW OF A STRETCH OF THE WATER FRONT OF THE MISSISSIPPI AT NEW ORLEANS.

THE PROPOSED LAKES-TO-THE-GULF WATERWAY.

canalize the river by building across it at stated intervals submerged dams which would change the total slope of 109 feet into a series of pools, with locks for passing the ships from one to the other This scheme is open to the objection that the enormous amount of silt brought down by the Missouri River, and the material from the constantly eroding banks of the river, would ultimately fill up the pools and necessitate heavy dredging The third method and probably the best would be to maintain the stream at a stated width between banks that were thoroughly protected with revetments

It is not unlikely that the ultimate solution of the problem will consist in a combination of the three methods suggested above It must not be forgotten, moreover that the volume of water available on this stretch during the lowest stages of the river will be increased by the 10,000 cubic feet per second discharged from Lake Michigan through the Drainage Canal Further presumptive evidence of the feasibility of the maintenance of not less than 14 feet throughout the year is to be found in the fact that the improvement work which has been carried on by the government engineers under limited appropriations for a number of years has shown it to be entirely possible to maintain a least depth of 8 feet throughout the period of the lowest stages of water

Cairo to the Gulf of Mexico - South of Cairo, the Mississippi enters the "great alluvial basin" and the question becomes one of keeping the river within its banks and controlling the floods. In this reach of the river the low water flow is 70,000 cubic feet per second which at high water increases to 1 600,000 cubic feet For over half the year except in years of unusually low water a depth of 14 feet is available The 300 miles of the river from Red River to the Gulf provides sufficient depth at all seasons of the year even for ocean-going ships, but from Cairo to the mouth of Red River, a distance of 165 miles there are obstructing bars which would have to be cut through to maintain the 14 foot depth.

For the past six years the engineers have had little difficulty in maintaining a 9-foot channel through these bars by dredging The Mississippi River Commission during 1907 maintained eight dredges at different bars during the low water season, in order to determine the possibility of maintaining a depth of 14 feet, and at three different points it was found possible to develop and maintain depths of 16 feet 17 feet and 16 feet respectively

The Pressing Need for the New Waterway—That the railroads are incapable of handling with facility and dispatch the business of the busy season was recently recognized by James J Hill, when he advocated increasing the trackage by the expenditure of $500 000 000 for new roads The necessities of the West however are so pressing that they cannot await the duplication of railway mileage, moreover the business men of the entire country who are interested in the movement of freight realize that the only permanent and economical solution of the various transportation problems is the improvement of the streams and rivers of the United States A complete system of waterways would act as a regulator of rates and as we have noted above, would serve to relieve the railroads of the more bulky freights which are the cause of the present congestion

That the Lakes-to-the-Gulf Waterway would be a beneficial and profitable enterprise is shown by a comparison of the freight movement by river and by rail from the port of St Louis for the years 1865 to 1900 the statistics of which gathered by J A Ockerson of the Engineers' Club of St Louis were published in the Report of the Mississippi River Commission for the year 1901 They show that the maximum rate on wheat by rail from St Louis to New York was 24 6 cents per bushel in 1877 and 11 6 cents per bushel in 1900 as against 8½ cents in 1877 and 4¼ cents in 1900 from St Louis to the seaboard at New Orleans Again the total number of bushels of grain exported from St Louis from 1883 to 1900, inclusive was 761, 004 715 The average rate per bushel from St Louis to Liverpool by the Mississippi and Gulf route was 6 85 cents less per bushel than by rail *via* Atlantic ports These figures show that the magnificent sum of over $52 000 000 might have been saved to the producer and shipper had the grain been carried by the river route

The possibilities of river traffic are shown by the two following illustrations The steamer "Sprague" a typical stern wheel towboat of the Mississippi River type, recently took down the river at one hand the cargo of 67,000 tons of coal It would have required nearly 2 000 cars containing the average carload to haul this single cargo Again the 'Harry Frank has carried 9 266 bales of cotton and a quantity of cotton seed at a single load This single cargo would have made 300 train carloads There is a wrong impression in the popular mind as to the relative speed of transportation by water and rail The "Sprague" took down her huge cargo in barges at a speed of from 75 to 100 miles per day, which is much faster than the average speed, as given by a high railway authority, of freight carried by rail.

It is our firm belief that the opening of a waterway 14 feet deep from the Lakes to the Gulf would not only cause an immediate development of the existing traffic, but that a type of steamer suitable for lake and river traffic would be built to meet the special requirements. Furthermore, we believe that the results would be so encouraging as to warrant, before many years had gone by, the expenditure of additional sums of money in increasing the depth of the channel to 20 feet for the accommodation of through shipments in bulk from lake and Mississippi ports to foreign countries.

Halley's Comet,

The total eclipse of the moon on the morning of November 27th was well observed by Prof Brooks at Smith Observatory, Geneva, N Y, the sky being unusually clear after a long period of clouds and storms As a naked-eye spectacle the eclipse was a very beautiful one the moon when immersed in the earth's shadow having the appearance of burnished copper All the different phases took place according to the predicted times as follows

	H	M
Moon entered shadow	2	11 A M
Total phase began	3	14 A M
Middle of eclipse	3	55 A M
Total phase ended	4	36 A. M
Moon left shadow	5	38 A M

The moon was in Taurus, and the occultation of a number of stars by the moon was observed

Several bright meteors from the Biela radiant, and which were due that night, were noted.

Most interesting of all, however was the observation of Halley's comet with the large telescope during the total phase of the eclipse During moonlight the comet was quite invisible even in the largest telescopes, it being yet quite a faint object But during totality the sky was quite black and on setting the telescope to the computed place Prof Brooks had this celebrated comet at once in the field of view Although faint and small, a mere misty spot with a central condensation and diffused edges, it was an easy object in the 10-inch aperture equatorial telescope But in a few weeks it will be considerably nearer the earth, and should be visible in moderate-sized instruments

The position of the comet on the morning of November 27th was right ascension 4 hours 44 minutes 10 seconds, declination north 16 degrees 18 minutes—a short distance south and east of the bright red star Aldebaran in the constellation Taurus

The comet is moving westerly through Taurus at the rate of about one degree daily, but changing very slightly in declination toward the south

A New System of Wireless Telephony

Prof Majorana has made his hydraulic microphone the basis of a new system of wireless telephony The hydraulic microphone consists essentially of a small glass tube, which is attached to a stretched membrane and serves as the outlet of a jet of slightly acidulated water, which is subjected to a certain constant pressure The descending stream passes, at a short distance below the outlet between two platinum electrodes establishing a connection, the resistance of which is modified by the local variations in the diameter of the stream which are produced by the vibrations of the membrane The electrodes and the liquid between them complete the circuit of a Poulsen generator which consists essentially of an electric arc in an atmosphere of hydrogen When words are spoken into the mouthpiece attached to the membrane, the arc emits aerial electric waves, which are in exact accordance with the sound waves striking the membrane, and from which the spoken words can be reconstructed, by suitable devices, at the distant station. Prof Majorana has experimented with a thermo-electric and a rarefied gas receiver, and has transmitted speech to a distance of nearly 200 miles

A Rule for Stairways.

BY A R. DIXON

In the building of stairways and ladders there is a simple little rule that is of general application and makes the most comfortable and practicable affair to climb It is

$$2 \times \text{the riser} + \text{the tread} = 24 \text{ to } 25 \text{ inches.}$$

For a ladder this gives a vertical distance between rungs of 1 foot, and the rule is based on the common-sense principle that it is more than twice as hard to lift as it is to go on the level but there is less of it to do

In a power plant the stairs should be straight in order to permit of handling long lengths of pipe, etc. In regard to width, 2 feet 9 inches is about the minimum, but the stairs are sometimes cut a little narrower, where room is available it is better to make the stairs 5 feet wide, which gives plenty of room for two to pass without crowding.—Power

A TREADLE BOAT.

To the Editor of the Scientific American

Back in 1856, when I was eight years old, my parents and I had to cross the Hudson River from Hudson to Athens, N Y We crossed in a ferryboat which was propelled by horses which worked a treadle beneath the upper or main deck. These boats were in common use at that time. From this you will see that what may seem curious to the present generation is in reality something that was very common half a century ago.

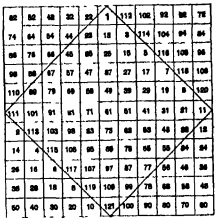
ANOTHER MAGIC SQUARE.

To the Editor of the Scientific American.

In the October 30th issue of the Scientific American you publish a certain five square which contains an inscribed diagonal square having all the odd numbers of the square within said inscribed square. Any square based upon a prime number can be arranged so



62	52	42	32	22	1	112	102	92	82	72
74	64	54	44	23	13	3	114	104	94	84
86	76	66	45	35	25	15	5	116	106	96
98	88	67	57	47	37	27	17	7	118	108
110	89	79	69	59	49	39	29	19	9	120
111	101	91	81	71	61	51	41	31	21	11
2	113	103	93	83	73	63	53	43	33	12
14	4	115	105	95	85	75	65	55	34	24
26	16	6	117	107	97	87	77	56	46	36
38	28	18	8	119	109	99	78	68	58	48
50	40	30	20	10	121	100	90	80	70	60

as to conform to the same conditions. Rummaging among a lot of eleven squares made some years ago, I found one having all the odd numbers in same general position but need a little transposition to render the odd numbers regular I inclose you the rearranged square, showing many interesting features besides the massing of the odd numbers

A Metallic Filter.

In all filters of the type of the Chamberland "candle the fine particles suspended in the liquid are retained rather by adhesion to the filtering diaphragm than by inability to pass through the channels which traverse the latter, as the diameters of these channels are much larger than those of the particles and microbes which are arrested The capillary forces are able to exert this filtering action because of the great length and irregularity of the channels of these filters of porcelain or infusorial earth The use of these filters is attended by two inconveniences.

1 After a longer or shorter interval (only 3 or 4 hours in some cases) microbes are found to pass the filter, either because their proper motions are too swift to be stopped by the capillary attraction, or because they multiply in the channels of the filter

2 The long and sinuous channels offer great resistance to the flow of viscous liquids, and this resistance, in contrast to the filtering power, continually increases

Gobbi has devised a metallic filter, the efficiency of which depends upon the narrowness of its channels and which removes microbes permanently, while the molecular adhesion is lessened by straightening the channels and diminishing their length.

The Gobbi filter consists of a strip of nickel 1/250 inch thick, about 1/16 inch wide and several hundred feet long, very finely corrugated transversely and rolled into a coil which can be tightened or loosened by a screw The filtering channels, formed by the opposed corrugations of the successive spires, are straight and only 1/16 inch long (the width of the nickel ribbon) while their diameter can be made less than those of the smallest known microbes by tightening the screw

This filter not only arrests all microbes during a period of several days but retains colloidal particles much smaller than microbes, so that solutions of dyes are completely decolorized by passing through the filter

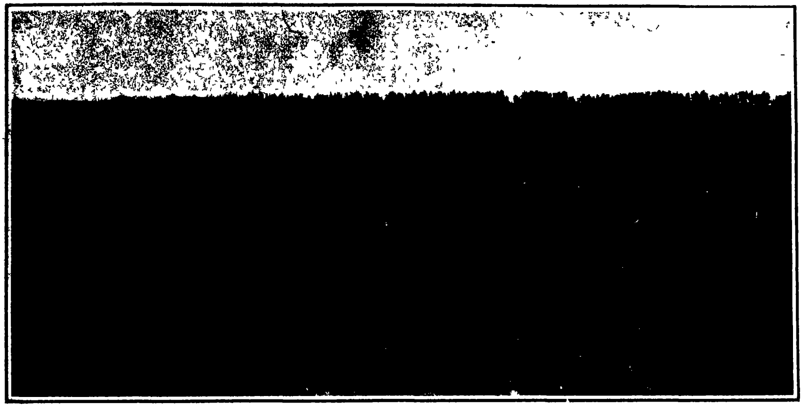
Several American railways are experimenting with mechanical stokers for locomotives. In very few cases have accurate tests been taken, and those that have show results unfavorable to the stoker. Where the firing is well within the capacity of one man without mechanical aid there does not appear to be much reason for installing mechanical stokers, although in America it is hoped that they will help to abate the black smoke nuisance.

American Harvesting Machinery—The Birth and Growth of a Vast Industry.

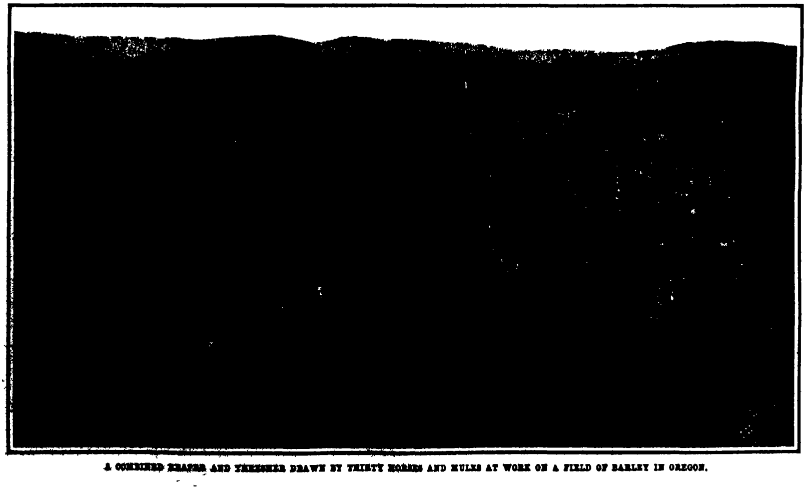


FORTY BINDERS AT WORK IN A WESTERN WHEAT FIELD

If the political economist is asked to designate the ultimate source of the wealth of the United States, he will point without hesitation to our vast agricultural interests. In colonial days and during the first three-quarters of a century of our life as an independent republic, we were essentially an agricultural people. With the introduction of the steam railroad and the development of our merchant marine, came the development of our manufactures, but these compared with our agricultural interests, were at first insignificant. With the introduction of Bessemer steel, however, we began to make rapid strides in all lines of manufacture, and during the past half century we have moved rapidly forward to the premier position among the great manufacturing countries of the world Nevertheless, it is a fact that to-day, in spite of our leading the world in manufactures it is customary for Wall Street to base its forecasts of the immediate prosperity of the country upon the predictions of the State Agricultural Department as to the prospect of the next year's harvest

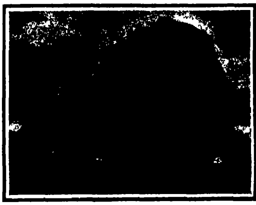
This fact of the close relation between the products of our farms and the prosperity of the nation as a whole is pretty well known to every American, but probably few people realize how greatly the development of the farm lands of the United States and the development of their full productive capacity has been due to the invention of special agricultural implements, and particularly of that marvel of ingenuity the American harvesting machine Originally designed to aid the farmer in developing sparsely populated districts in his own country, in which the amount of available manual labor was sadly disproportionate to the vast area brought under cultivation American agricultural machinery has been shipped in enormous quantities to every agricultural country in the world and has been undoubtedly the most potent factor in developing the vast cultivable areas of every continent of the world

For the beginnings of the agricultural implement industry as we know it to-day we must go back to the year 1831 and to the State of Virginia where Cyrus H McCormick built the first practical grain-harvesting machine Compared with the modern harvester it was but a crude affair Nevertheless, it contained the essential elements that have been found in every grain harvester that has proved a success from that day to this The parent machine had a main wheel frame from which projected to one side a platform containing a cutter bar having fingers through which reciprocated a knife which was driven by a crank. Upon the outer end of the platform was a divider which separated the grain to be cut from that to be left standing Above the platform was placed a reel which served to hold the grain against the reciprocating knife and throw the cut grain back upon the platform The machine was drawn by a team which walked by the side of the grain This machine was successfully operated on the farm of John Steel near Steel's tavern in the summer of 1831 The farmers of those days were proverbially conservative and it is amazing to learn that it was not until 1840 that Mr McCormick succeeded in making his first sale It was not until he had gone personally on horseback among the farmers of Indiana, Illinois Ohio and Kentucky and obtained from them written orders for

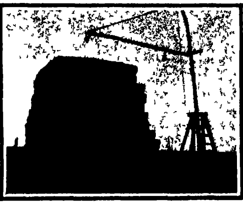


A COMBINED REAPER AND THRESHER DRAWN BY THIRTY HORSES AND MULES AT WORK ON A FIELD OF BARLEY IN OREGON.

his machines, that he induced a firm in Cincinnati to take up their manufacture.



A 100-TON STACK OF ALFALFA RAISED ON IRRIGATED LAND.

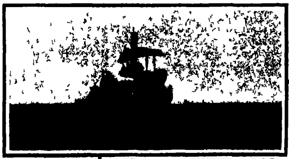


BALED HAY RAISED ON IRRIGATED LAND, TRUCKEE, NEVADA.

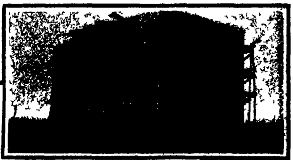
MACHINE LOADING ALFALFA AT LODI, CALIFORNIA.

The next step in the development of the reaper of 1831 was the addition of the raker's seat, a device invented by McCormick in 1845, by which the raker could be carried upon the machine and rake the grain from the platform to the ground. In the spring of 1851 McCormick exhibited his reaper at the World's Fair at London, and was awarded the Grand Council Medal. On this occasion the judges referred to the reaper as being worth to the people of England the whole cost of the exposition. At a later exposition McCormick received from the French government the decoration of the Legion of Honor for having done more in the cause of agriculture than any living man.

The next step was taken in 1849, when the Mann brothers of Indiana added a series of endless bands for carrying the grain, after it had been cut and reeled upon these bands, to the side of the machine, from which it was dumped upon the ground. In the same year Jonathan Haines brought out the first "header," which was pushed ahead of the horses, clipping the heads of the wheat which were carried on endless aprons to the side of the machine and deposited in wagons.



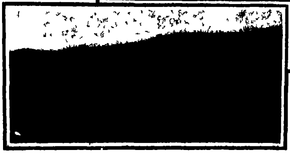
GANG OF PLOWS DRAWN BY A POWERFUL STEAM TRACTION ENGINE. ON THE LARGER FARMS STEAM IS RAPIDLY REPLACING HORSE POWER.



TYPE OF ELEVATOR ERECTED ON IDAHO RANCH FOR INDIVIDUAL USE. FROM THESE ELEVATORS THE GRAIN IS SHIPPED BY RAIL.

TYPICAL OUTFIT ON A LARGE OREGON FARM

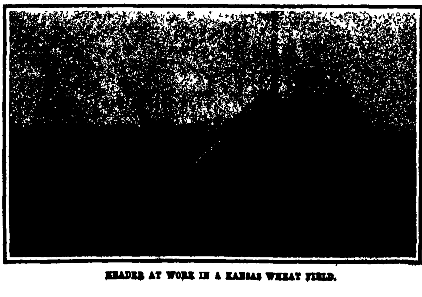
In 1850 Adams and Gifford built the first hand-binding harvesting machine, which contained a platform upon which the grain fell from the endless apron, where it was bound by men carried upon the reaper.



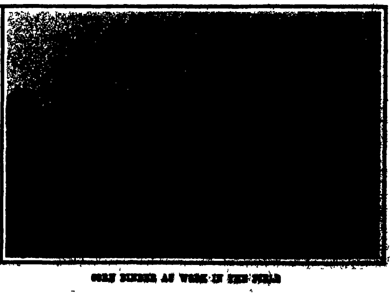
THRESHING GRAIN AT CARSON, NEVADA.

BALING HAY AT FALLON, NEVADA.

The next stage of development toward the modern self binding harvester was the attachment of a binding device to take the grain that had been cut and raked into gavels, and bind the same automatically into bundles, the patent for this device being taken out by Heath of Ohio in 1850. Then came Jacob Bethel in 1864, who patented the knotting bill which loops and forms the knot, and the turning cord holder for retaining the end of the cord, and later in 1873, after associating himself with A. Wood, he built and sold what was probably the first automatic self binding harvester that was ever put upon the market. After various attempts had been made to use wire for binding, Gorham in 1874 put in the field the first successful automatic self-sizing binder. This remarkable machine contained the essential elements of the McCormick reaper with the ingenious grain binder added. The grain is delivered upon a platform, where it is seized by packers, carried forward into a secondary chamber, where it is compacted by the packer against a yielding trip so arranged that when sufficient grain is accumulated the trip yields and starts the binding mechanism into operation. The cord is carried on the machine in a ball. The grain is forced against this cord by the packer, and when the binder starts, the needle encircles the gavel, carrying the cord to a knotting-bill of the Bethel type. Here the end is again seized by the



HEADER AT WORK IN A KANSAS WHEAT FIELD.



CORN BINDER AT WORK IN THE FIELD

rotating holder, the loop formed, the ends of the bands severed, and the bundle is discharged, bound, from the machine. At the same moment a gate, which, during the binding operation, has shut off the flow of grain, retracts, and the operation is again repeated.

In the thirty-five years since the production of the first successful self-binder, the progress in the development of the harvester has been in the direction of improving its mechanical details and increasing its size and capacity Originally, the threshing of the grain was done by separate threshing outfits which traveled from farm to farm for this purpose, but with the opening up of the huge wheat ranches of the West, there has been developed and brought to great perfection a combined harvester and threshing machine several illustrations of which are herewith reproduced These wonderful machines cut, thresh, and sack the grain at one operation As they travel through the field, one sees the cutting bar, 15 to 25 feet in length, slicing its way through the standing grain and on the other side he witnesses the steady delivery of the grain in sacks ready to be hauled to the railway elevator The largest of these machines are to be found in operation on the Pacific coast They are either hauled by teams of from thirty to forty horses, or by large steam traction engines The biggest of these, a Best machine, is hauled by a traction engine of 110 horse-power The cutting bar is 25 feet long the separator or thresher measures 54 inches, and has a capacity for cutting and threshing 65 to 100 acres of wheat per day, the amount depending upon the condition of the grain to be harvested The cutting bar of the horse-drawn machine is 16 feet long, and the thresher measures 36 inches. This machine can cut from 35 to 40 acres per day The harvesting expenses when using the steam harvester, are from 35 cents to 60 cents per acre, and the horse-drawn machine operates at an expense of from 60 to 70 cents per acre

There are but few statistics obtainable with relation to the early growth of grass-cutting and grain-reaping machinery In 1840 there were three reapers made, and less than that number of people were employed upon them In 1845, 50 people were employed in the manufacture of 500 machines. In 1850 the production had increased 3,000, and in 1860 20 000 machines were produced, in the manufacture of which 2,000 people were employed About the year 1880 shortly after the automatic cord binder was perfected there was an immediate and marked increase in the output so that by 1885 there were more than 100 000 self binding harvesters built and sold, and 150 000 reapers and mowers 20 000 people being engaged in their production

Although the American harvesting machine has exerted the most potent influence in the development of the arable lands throughout the world there has been a similar advance in the improvement of other agricultural implements and a similar growth in the magnitude of the industry devoted to their manufacture For the following statement of the progress made as shown by a comparison of methods old and new, we are indebted to Mr M. R B Owings, of the International Harvester Company

This machine cuts the wheat, threshes it, and delivers it ready sacked in one continuous operation.

REAR VIEW OF A 50-HORSE-POWER HARVESTER COMBINE

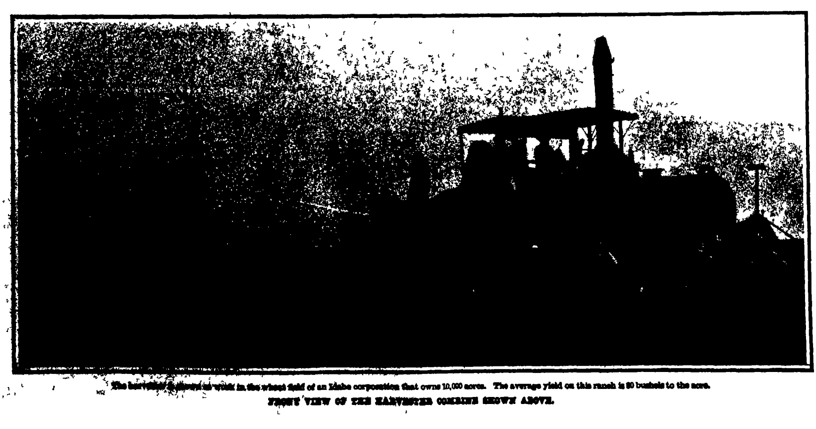
PLOWING BY OLD METHODS AND NEW —The old wooden beam walking plow has been superseded by the modern steel beam riding gang plow Throughout the great Northwest, and in nearly all the region west of the Mississippi River, the plow drawn by a traction engine has long since passed the experimental stage Several 16-inch plows are drawn by a 20-horse-power traction engine. On a large farm where three or four such outfits are in operation at the same time it is not difficult to understand how thousands of acres of good wheat land can be plowed, harrowed, and seeded within a comparatively short time, for tractors are also used to operate seeding machines, both the pulverizing and seeding being done in one operation With the old style plow two acres per day could be plowed at the cost of $2 50 per acre With the gang plow drawn by gasoline tractor one and one-fourth acres can be plowed in an hour at the cost of 75 cents an acre If the plows are drawn by a steam tractor, the cost is $2 per acre.

SUMMARY OF THE AGRICULTURAL MACHINERY INDUSTRY 1850-1895

	Census			
	1905*	1890	1870	1850
Number of establishments	648	910	2,076	1 333
Capital	$196,740 700	$145,313,997	$34,834 600	$3,564,202
Salaried officials clerks etc number	7 109	[illegible]	(4)	(4)
Salaries	$7 578,640	[illegible]	(4)	(4)
Wage earners average number	47,394	[illegible]	25,249	7 220
Total wages	[illegible]	[illegible]	$12 151 504	$2,167 868
Miscellaneous Expenses	[illegible]	11 159 548	(6)	(6)
Cost of materials used	46,261 106	31 019,265	21 473,925	2,445 765
Value of products.	112,007 344	[illegible]	52 066 875	6,842 611

* Exclusive of the statistics of 95 establishments engaged primarily in the manufacture of other products These establishments made agricultural implements to the value of $1,319 679

THRESHING MACHINES —The threshing outfit commonly used thirty years ago consisted of the old fashioned separator and the now antiquated horse power There were one or two band cutters and one or two feeders according to the width of cylinder were required to feed the grain into the machine three or four men measured and sacked the grain while three



The harvester is shown at work in the wheat field of an Idaho corporation that owns 10,000 acres. The average yield on this ranch is 30 bushels to the acre.

FRONT VIEW OF THE HARVESTER COMBINE SHOWN ABOVE.

to six men were kept busy stacking the straw in a cloud of choking dust

The modern threshing machine is equipped with an automatic band cutter self feeder, automatic weighing and sacking device and pneumatic swinging straw stacker the necessary power to operate all of which being either a gasoline or steam traction engine By the old method of growing wheat, the time required to produce a bushel is three hours The modern harvesting machines can cut the time down to ten minutes the old cost being 17¾ cents per bushel, as compared with 3½ cents per bushel now The old threshing machine had a capacity of 175 to 225 bushels per day the modern machines can handle 2 000 bushels and over in the same time

Haying Machines—A similar advance has been made in machines for handling the hay crop The old revolving wooden tooth hay rake has given place to the self-dump sulky steel hay rake This machine can be operated by a ten year-old boy who can do more and better work than could a man using the old method The hay tedder enables the farmer to cure his hay quickly and greatly improve the quality of the hay By means of the hay loader, timothy clover or alfalfa can be taken direct from the swath and loaded on the wagon With the modern sweep rake the hay can be taken direct from the swath or cock and put into the stack with the hay stacker Extensive use is also being made of the derrick hay fork especially when the hay is to be put away in the mow

Corn Machines —Thirty years ago much of the corn crop was planted by hand cultivated with a one horse walking plow cut by hand with the corn knife and put into the shock by main strength and awkwardness To-day the check rower automatically plants the corn in hills exactly the same distance apart so that the corn will be in rows no matter in what direction you may look at the field in other words the young corn can be cultivated with a riding sulky cultivator both ways east and west as well as north and south which of course thoroughly destroys all weeds When the crop is matured the modern corn binder cuts and binds the corn into bundles ready to be put in the shock One man with a corn knife can cut about one acre of corn in a day the modern corn binder cuts and binds six to ten acres in a day

The corn husker and shredder has been developed and perfected within the last twenty years This wonderful machine enables the corn grower to double the value of his corn crop Heretofore corn has been husked by hand and the stalks have been allowed to stand in the field and go to waste, for cattle will not eat standing corn stalks Cutting corn by hand was a slow and laborious task at best but with the modern corn binder the farmer can cut his corn crop promptly at the time when the nutritious juices are still in the stalk With the husker and shredder he can husk his corn and shred the stalks leaves and husks into stover which can be put away in the mow the same as hay or can be baled Cattle horses and sheep can be fed on shredded fodder all winter and they will be kept in good condition without any other feed In the United States nearly one hundred millions of acres are devoted to growing corn About two tons of corn stalks are grown on every acre The modern improvements made in the machines used for handling the corn crop make it possible for the farmer to save two hundred million tons of corn fodder which when shredded into stover is fully equal in feeding value to good timothy hay At the low estimate of $5 a ton the husker and shredder alone if the whole corn crop were shredded would annually add one billion dollars to the agricultural wealth of the country The corn sheller enables the farmer to shell his corn quickly if he does not wish to market his crop in the ear

Cream Separator.—In the old days the milk was strained into crocks and put away in the cellar over night The cream was skimmed from the crocks and laboriously churned into butter by hand This old method left the skimmed milk almost valueless—cold sour and diluted to such an extent that it had little value for feeding purposes When the cream separator is used the skimmed milk is both sweet and warm and is much relished by calves and pigs A great deal of work involved in handling the milk is saved by the use of a cream separator The milk does not have to be carried into the house or to the cellar or to the spring or cooling tank there are no unnecessary cans crocks pans and other vessels that must be washed The cream separator enables the farmer to double his dairy products with less than one-third of the work involved in handling the milk the old way The yearly income from a good cow should be $89 25 Under the old methods the yearly loss was $22 which is altogether eliminated by the use of the cream separator

Gasoline Engine -Among the improvements which have helped to transform drudgery to a pleasurable pastime on the farm the gasoline engine must be given a prominent place When we were boys on the farm nearly all the odd jobs were done by hand The wood pile and the corn crib were always full of terrors for the average farm boy, but the gasoline engine has wrought a magical change. This mechanical handy man will furnish power to operate the cream separator, to churn, and to feed the ensilage cutter, and it will saw the wood and shell the corn, and do innumerable other chores that are familiar to everyone who has been brought up on the farm. The gasoline engine is both an economical and reliable power and it needs but little attention A 10-horse-power engine of good design uses about one gallon per hour when doing its full 10-horse-power work. The trolley car and the telephone are doing much to bring the farm into closer touch with the larger cities but it is the gasoline engine that is doing most to keep the boy on the farm. It is made in various styles and sizes, to suit the needs of the ten-acre farm as well as those of the ten thousand-acre ranch

Manure Spreader.—A great deal has been written about the abandoned farms of New England, and were it not for the improvements made on the manure spreader now so generally used, the same doleful story would be written about many farms in the Ohio Mississippi and Missouri valleys This region has always been known as the garden spot of the world, but even the marvelous fertility that is so common in Illinois Ohio Iowa, Missouri and other States, noted for their bounteous crops would soon become exhausted if the soil were not replenished with plant food The manure spreader makes it possible for the farmer to renew the fertility of his soil every year Instead of growing fifteen bushels of wheat to the acre, he fertilizes his ground properly and reaps a harvest that will average thirty bushels to the acre indeed many fields have been known to yield as much as fifty bushels per acre

The modern farmer is working with a well-defined purpose His constant aim is to do less work that requires muscle and brawn but more brain work He purposes to purchase machines that will do the drudgery and irksome tasks while he himself can find time to solve the problems of farm management. A little head work properly applied to the management of a farm will often turn loss into profit.

A Zeppelin Polar Expedition

The object of the Zeppelin Polar Expedition Society recently organized in Germany, is sufficiently explained by its title The executive committee has decided to send a preliminary expedition to Spitzbergen, in the summer of 1910 for the purpose of studying the ice of the polar sea and determining the conditions which must be satisfied by a dirigible balloon operating in the polar regions The committee attaches great importance to new improvements which will enable Zeppelin balloons to make long journeys and deems it necessary to make preliminary voyages over sea in order to solve numerous problems which are very important to the practice of aeronautics in such conditions An airship will be at once designed for oversea flights and should be completed by the beginning of the year 1911

It might be thought that as Peary and Cook have reached the pole—and found nothing there, as could have been foreseen—it is useless to send out a polar expedition in an airship but this view would be erroneous In previous expeditions the explorers have had neither leisure nor facilities for the collection of important scientific data If the Zeppelin expedition is successful its members will be less hampered by lack of time, and less exhausted by fatigue and privation Hence they may be expected to make scientific observations of great value

Aging Wines with Ozone.

The quality of wine is greatly improved by natural aging in wood or glass, but this method keeps a large amount of capital unemployed and involves a loss of 4 or 5 per cent by evaporation The same improvement in the wine can be accomplished more rapidly by the action of oxygen Boussingault proved that exposure to oxygen makes new wine less acrid and hastens the deposition of impurities in the form of lees It is asserted furthermore that wine does not improve by age either in wood or in glass, unless it has already absorbed a certain quantity of oxygen from the air and Pasteur has proved that wine deprived of oxygen is not altered by keeping

Artificial aging has often been tried but it has been found impossible to obtain the desired result by the introduction of either pure oxygen or pure ozone The process patented by Alfred Dorn a few years ago, appears to be more successful It consists in the introduction of oxygen and its transformation into ozone in the interior of the mass of wine A tubular electrode connected with an oxygen tank and an induction coil is inserted into the cask, and a portion of the oxygen thus introduced is converted into ozone by the electric current The operation is continued for a period varying from twenty to ninety minutes, according to the quality and quantity of the wine. For distilled spirits it may be necessary to continue the treatment six hours. This rapid treatment must be followed by natural aging for a short time, but new Bordeaux wine acquires by this method, in from forty to sixty days, the quality of wine kept for many years in bottles.

Rats and Petroleum.

The treatment of stagnant water with petroleum, which is effectual against mosquitoes, operates also in an indirect manner on rats Mr Mandoul has made investigations on board "L'Imerethie" during September, 1907 These are abstracted in the Archives de Parasitologie One of the holds of the ship, which contained silk cocoons, had been almost entirely devastated by rats. Their presence there had probably been due to the saccharine water from the fruits and ice placed near the hold in question To this body of water which it had been impossible to remove, petroleum was added. Two weeks later, on arriving at Marseilles, it was found that not one cocoon had been damaged by the rodents Mr Mandoul sought to find out how the petroleum had been so efficacious, he endeavored to determine the sensitiveness of the rat to petroleum A sewer rat was subjected during about forty five minutes, to the action of the vapor of about 100 grammes of commercial petroleum in a closed atmosphere (a bell communicating with the exterior by a narrow orifice) The animal began to exhibit labored breathing and during the last quarter hour, a lassitude in its movements After these manifestations the animal licked the hairs of its beard, it was depressed and ate little Three days afterward it was found dead in its cage The autopsy showed that its viscera were very congested and that the intestines contained some petroleum Another rat was subjected to a diet of petroleum It refused bread treated with petroleum, but accepted meats. It died after about a quarter of an hour The author made inquiry in petroleum refineries, and upon boats which transport this product. Rats do not exist there or are very rare Mr Mandoul concludes that rats have a peculiar aversion for petroleum, which drives them away rather than poisons them, the aversion with which they are inspired resulting from their desire to seek shelter from its toxic action In addition the petroleum, thanks to its insecticidal effect, rids the rats of their parasites and of the infectious germs which they are able to transmit

Chicory Coffee.

At the Congress of the French Association for the Advancement of Science, which was held in Lille Mr P Dorveau gave a communication in which he studied the history of the usage of the roasted root of chicory, as a substitute for coffee—we are inclined to say, as an adulteration of coffee

The author of this invention is unknown, perhaps he was not willing that future generations should know the name of him who conceived what many consumers cannot fail to call a misdeed, it is true that the growers of chicory, and the manufacturers thereof, have worked hard to erect a statue for him.

Not only is the name of the inventor unknown, but even the date of the invention has been seriously disputed, and is a question which has long been discussed After examining the documents, Mr Dorveau believes he has been able to establish that the Dutch used chicory in 1690 There was a delay of almost a century before its usage spread beyond the country of its origin, the Prussians were the first to adopt it in 1763, the French have been making use of it since 1771, and there has been a singular development of the usage of chicory in France since that date.

Valmont d'Bomare, in praising the usage of chicory in his dictionary of natural history, published in 1775, without doubt contributed more than anyone else to its widespread use

How Long Will the World's Supply of Iron Last?

Less than 2 million tons of iron ore was mined in 1800, less than 11 million tons in 1850, and nearly 85 million tons in 1901 Some day the world's supply of iron will be exhausted and the question, when this day will come, has already been discussed According to Prof Bins, the total quantity of iron ore contained in known and workable deposits amounts to about 8 000 million tons, distributed as follows Germany, 2,200, Russia, 1 500, France, 1,500, United States, 1 100, Sweden, 1,000, Spain, 500, England, 250 million tons. As an annual production of 50 million tons of iron means an annual consumption of from 100 to 150 million tons of ore, [illegible] entire available supply of iron ore, as estimated above, will be exhausted before the close of the twentieth century Apart from the fact that [illegible] regions of the earth have not yet been explored [illegible] search of mineral deposits, this conclusion appe[illegible] too pessimistic for the reason that even very [illegible] iron, which are not now worked but could be wor[illegible] case of necessity, exist in great abundance. Hence an exact answer to the question appears to be neither necessary nor possible, at present.

Gary: The Largest and Most Modern Steel Works in Existence.

The rapid increase in the business of the United States Steel Corporation rendered it necessary, some four years ago, to make a considerable increase in its plant. The more or less congested conditions surrounding the various existing establishments led the company to search for a site where a large area of land could be purchased at a reasonable price, and which would be located within economical hauling distance of the great centers from which the supplies of ore, coke, and limestone could be derived Such a location was found in the State of Indiana on the south shore of Lake Michigan, some twenty five miles south of the city of Chicago Here the company purchased a tract of over 9,000 acres, with a frontage on Lake Michigan of seven miles. One thousand acres of this property, including a water front two miles in extent, was selected as the site of the new steel plant. The property was a dreary waste of drifted sand, entirely uninhabited and covered with a scanty growth of grass and scrub timber It was an ideal location for the purpose, for on one side it was accessible by the ore-carrying steamers from Duluth and on the other side it was served by several trunk railroads over whose tracks the coke and limestone could be brought in and the finished products hauled away without any intermediate handling or trans-shipment.

With such a virgin site to build upon the designers of the plant were able to work with a free hand, and the component parts of this, the greatest steel plant in existence, were therefore laid out with a strict regard to the economical handling of the enormous masses of raw material and finished product It can be understood that where the total tonnage of material handled in any industrial establishment runs into the millions, it is of the highest importance that this material shall pass from process to process, from building to building, with as little handling and as short a haul as possible, and in laying out the huge open-air structure and inclosed buildings which cover the 1 000 acres that include the present plant, strict attention was paid to this feature. Furthermore, advantage was taken of several recent improvements in the art of steel manufacture, notably that of utilizing the blast furnace gases in gas-driven power plants to operate the blowing engine and provide electrical power for the operation of the various mills. Apart from the vast extent of the plant the feature which has attracted the attention of the engineering world to the Gary steel plant is the great economies which have been effected by the use of gas-driven engines of great size for the generation of practically all of the power required for operating the machinery The plant is owned by the Indiana Steel Company, to whose vice-president Mr G G Thorp, we are indebted for assistance in the preparation of the present article

Work was commenced in March, 1906 and at the present time over one-half of the plant has been completed and is in operation The work of construction is being steadily prosecuted and when the whole work is finished the equipment will be as follows

A harbor, with complete ore-unloading facilities, and a storage yard capable of accommodating 5,000,000 tons of ore

Sixteen modern blast furnaces, having an annual capacity of 2,400 000 tons of pig iron

Six open-hearth furnace buildings, each containing fourteen 60-ton furnaces. The combined annual capacity of this plant is 3,750,000 tons

A billet mill and a rail mill the largest in the world, capable of turning out 4,000 tons of rails per day, plate mills, an axle-making plant, and a large group of merchant mills, the above plants having a combined capacity sufficient to roll all of the steel that can be produced in the open hearth furnace plants.

A blowing plant of a total capacity of 92,000 horse-power for furnishing air to the blast furnaces, operated by gas engines of 64,000, and steam engines of 28,000 horse-power total capacity

An electric power plant, driven by gas engines of a combined capacity of 120,000 horse-power, for operating the various mills.

A complete equipment of mechanical shops at which all of the repairs can be made and much of the machinery required by the plant.

A water supply system, served by two 10-foot conduits leading from Lake Michigan, whose pumps are capable of supplying 170,000 gallons of water per day under a head of 120 feet.

A railway system extending throughout the plant which includes 125 miles of standard railway track.

TOWN OF GARY

Adjoining the steel plant the company has built an entirely new town for the accommodation of its employees Already it houses some 15,000 people, of whom about one-third are employed at the works and includes about 500 dwellings, three hotels and a school house built by the company Also many dwellings and business blocks have been erected by private persons The town has been laid out on the most approved modern lines with broad brick paved concrete or macadam streets and cement sidewalks It contains its own waterworks and gas plant and the whole town is lighted from a large generating station in the steel plant Space has been reserved for two recreation parks and everything is being done to render this city comparable with the best model industrial cities of the country

THE ORE DOCK AND UNLOADING APPLIANCES

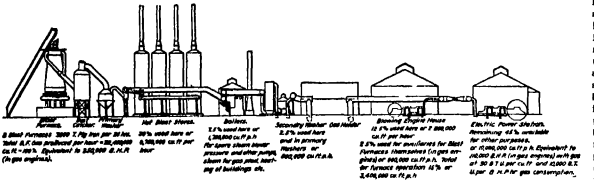
When the ore steamers from Duluth arrive at Gary, they enter an artificial canal 22 feet deep and 250 feet wide, which extends at right angles with the shore line for a distance of 4,650 feet inland when it widens out into a 750 foot diameter turning basin The west bank of the canal adjoining the steel works is formed by a massive concrete retaining wall back of which extending parallel with the canal, are the ore unloaders the ore handling bridges and a vast open concreted area with concrete walls on either side for the storage of the ore for winter use The completed plant will include ton unloading machines of the Hulett type Each machine consists of a massive walking beam at the outer end of which is a vertical arm ending in a 10-ton grab bucket The steamer is moored alongside the concrete bulkhead, and as soon as the hatches are off the unloaders thrust their 10-ton buckets into the holds, bring up the ore and deliver it to a conveyer car which runs back and discharges it into a trough on the edge of the stockyard, or into a hopper on the machine from which it can be shot into cars The machines will have a combined unloading capacity of 2 500 tons of ore per hour Working in conjunction with the Hulett unloaders will be ten Hoover & Mason traveling conveyor bridges These huge structures five of which are shown in our panoramic view of the steel works are about 500 feet long They extend from the concrete trough before mentioned into which the Hulett unloaders discharge clear across the whole width of the stockyard Each bridge is provided with a 15 ton grab bucket by which the ore is picked up from the trough and deposited in the stock pile from which it is picked up again as it is needed and loaded into the blast furnace supply cars The object of the huge storage yard which is 4 000 feet in length is to enable the company to provide a sufficient supply of ore to operate the plant during the five months of the year when lake navigation is suspended Its total capacity is about 5 000,000 tons

THE BLAST FURNACES

Back of the stockyard and extending parallel with the same are eight blast furnaces (to which eight more will be added), each with its equipment of four hot blast stoves The blast furnaces are 88 feet in height from the tap hole from which the hot metal is drawn to the top of the furnace lining, and the capacity of each is 450 tons per day

Between the stock pile and the furnace is a long line of elevated storage bins arranged in two parallel rows. One row is for coke and the other for ore and limestone. Above the bins are four tracks on which travel two 60-ton electric transfer cars. The ore is loaded into the transfer cars by the buckets of the overhead ore bridges. The coke and limestone are brought up over the bins by rail and deliver their load directly by gravity At the bottom of the bins are spouts controlled by electrically operated gates and below these are tracks which run the full length of the bins Traveling on these tracks are electrically operated lorries into which the ore, coke and limestone are delivered from the bin spouts. The lorries carry the materials to what are known as the "furnace skips," of which there is a pair to each furnace The skips run upon an inclined railway which runs direct from a pit below the transfer cars to the charging platform at the top of the blast furnaces Each trip of the skip is made in about 60 seconds and its average load consists of about 7 000 pounds of ore or 6 000 pounds of limestone, or 3 600 pounds of coke The operator merely starts the skip on its journey Its journey up the incline and the halt at the charging platform above are purely automatic

The blast furnace is a huge steel shell lined with a thick wall of firebrick Its interior diameter is 15 feet at the base or hearth 21½ feet at a height of 13 to 21 feet above the hearth 16 feet at the top It is loaded full with a charge of coke limestone and iron ore The air for combustion is introduced through a series of water cooled tuyeres which enter the furnace near the top of the hearth This air is supplied by huge blowing engines at an average pressure of 18 pounds per square inch Part of the hot gases from the top of the furnace after first having been cleaned in the primary washers are led through the hot stoves of which there are four to each furnace as shown in our panoramic view of the plant The stoves are huge cylindrical plate steel structures filled with a honeycomb of firebrick The burning of the gases in the stove raises the temperature of the firebrick and when this has reached a certain point the gases are cut off from that stove and turned into another one of the series. At the same time the cold air from the blowing engines is caused to pass through the now heated firebrick of the first stove where it takes up the heat given up by the combustion of the furnace gases and returns it to the blast furnace The operation of the blast furnace is continuous and the temperature varies from that of the molten iron in the hearth at the bottom to that of the cold charge which has just been introduced at the top As the charge is reduced it gradually descends as molten metal and as slag the slag because of its lighter weight, floating on the top of the molten metal At regular intervals the slag and the metal are separately drawn off into ladles the slag being hauled to the slag pile and the metal being taken to the mixers or cast into pig metal as hereafter described Each furnace at Gary has a capacity of 450 tons per day



Blast Furnace.
Dust Catcher.
Primary Washer.
Hot Blast Stoves.
Boilers.
Secondary Washer.
Gas Holder.
Blowing Engine House.
Electric Power Station.
8 Blast Furnaces 3000 T. Pig Iron per 24 hrs. Total B.F. Gas produced per hour = 22,450,000 cu. ft. = 100%. Equivalent to 320,000 B.H.P. (In gas engines).
30% used here or 6,735,000 cu. ft. per hour
7.5% used here or 1,700,000 cu. ft. p. h. For spare steam blower pressure and other pumps, steam for gas plant, heating of buildings etc.
2.5% used here and in primary Washers or 560,000 cu. ft. p. h.
12.5% used here or 2,800,000 cu. ft. per hour
2.5% used for auxiliaries for Blast Furnaces themselves (in gas engines) or 560,000 cu. ft. p. h. Total for furnace operation 15% or 3,400,000 cu. ft. p. h
Remaining 45% available for other purposes, or 10,000,000 cu. ft. p. h. Equivalent to 110,000 B.H.P. (in gas engines) with gas at 90 B.T.U. per cu. ft. and 10,000 B.T.U. per B.H.P. hr. gas consumption.

DIAGRAM SHOWING THE DISTRIBUTION OF THE FURNACE GASES AT GARY

CLEANING AND DISTRIBUTION OF BLAST FURNACE GASES

The most striking novelty in the Gary steel plant is the substitution of gas engines for steam engines in producing the enormous quantity of power necessary for operating this huge establishment The blowing engines which supply air for the blast furnaces are operated in part by gas engines of a total of 64 000 horse power and all of the mills are driven by electric motors current for which is produced by electric generators driven by gas engines of the largest size and of a combined capacity of 120 000 horse-power

Originally in the early days of steel making the gases were allowed to escape from the top of the blast furnace and go to waste Then the tops of the furnaces were closed and the gases were conducted to large boiler houses where they were used to raise steam for driving the steam blowing engines throughout the plant In the latest improvements as installed at Gary the whole of the gases are utilized The diagram shown herewith gives the distribution of these gases, and it should be remembered that the figures given are for eight furnaces only which together produce 22 450 000 cubic feet of gas per hour When the whole sixteen are running the total production will be about 45 000 000 cubic feet per hour Of this amount 30 per cent is used in heating the hot stoves in which as we have seen the air is heated before entering the blast furnaces The steam boiler plant uses 7.5 per cent 2½ per cent disappears in the gas washers the blowing engines 12½ per cent and 45 per cent is available for the gas engines in the electric power station All the gas from the top of the blast furnaces first passes through dust catchers and a primary washer which remove the larger part of the solid impurities and that part of the gas which is burned in the hot blast stoves and under the boilers goes direct from the primary washer to its destination The gas which is destined for the gas engines passes through another washing plant of which there are four to each pair of blast furnaces The gas is thus

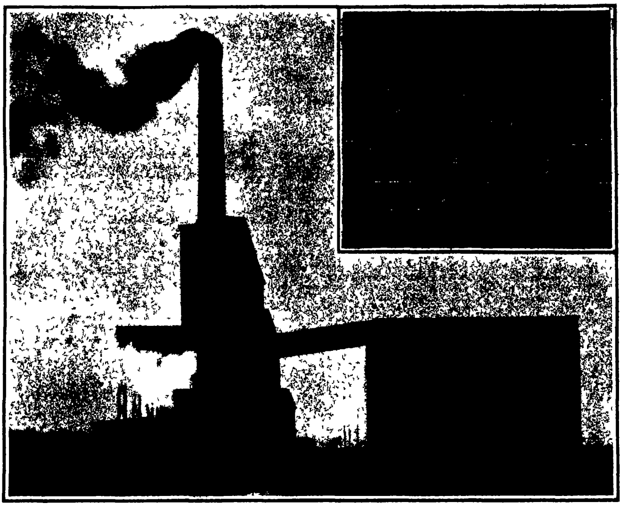
The Handling and Storage of Our Huge Grain Crop.

Few people outside of those who are connected with the garnering handling transportation and distribution of our grain crop appreciate either its magnitude or the wonderful plant and organization which are required for its transfer from the farm to the consumer's table The latest available statistics are those for the year 1908, and they give the crop return as follows corn 2 612 687 000 bushels spring and winter wheat 659,030 000 bushels, oats, 789,161,000 bushels Adding to these totals those for barley, rye, and buckwheat, we get as grand total for the year 4 304,689 000 bushels.

In view of these figures one can readily understand that the acreage in the United States which is devoted to the raising of maize wheat etc has about trebled during the past thirty years The increment has taken place chiefly in the great Middle West, and more particularly to the west of the Mississippi River in the Dakotas in western Kansas, and in California, Oregon and Washington The section of the United States which includes these new farm lands is one of magnificent distances The fields of golden grain are scattered over an area that is measured by square miles in the hundreds of thousands When the fostering care of the farmer has brought the grain to its full maturity he is confronted with the tremendous problem of finding not only a market but one in which the price will be amply remunerative for his twelve months of labor These four billion bushels of grain must be gathered together to certain distributing centers and thence sent out to the millions of consumers who are scattered throughout the habitable globe It is evident at a glance that in this as in every problem of a commercial character involving the handling of a vast tonnage made up of widely scattered units, the question of profits will be directly determined by the systematic skill and suitable machinery and plant employed for such a colossal task. The solution of the problem has been found in the American elevator and the distinctively American system of freight transportation by railroad. Both of these have been developed along lines which have enabled the United States to handle wheat with an economy and dispatch which is not to be matched in any part of the world

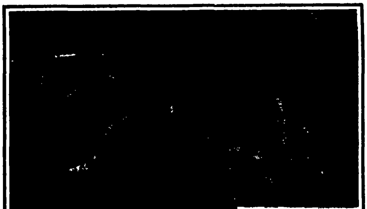


The working house. Upper view shows building of the concrete bins.

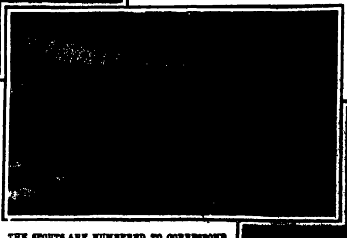
SANTA FE ELEVATOR AT ARGENTINE, KANSAS. CAPACITY, 1,000,000 BUSHELS.

By way of illustrating the methods by which our grain crop is handled we will follow the course of a consignment of grain from a farm on the western prairies across the broad American continent and out to sea.

In the description which follows we wish to express our indebtedness to the John S Metcalf Company engineers, of Chicago, for photographs and descriptive matter of several of the huge elevators which they have built for various companies.



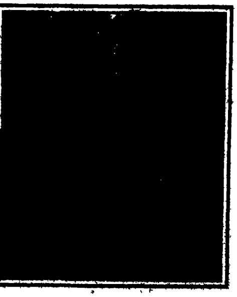
BELT CONVEYER AND TRIPPING MACHINES FOR DISCHARGING WHEAT FROM BELT



THE SPOUTS ARE NUMBERED TO CORRESPOND WITH DIFFERENT BINS

The first step in the journey is seen in the farmer's wagon jolting with its load of wheat along a country road, let us say in Dakota to the nearest railway siding Here the wagon is driven up an incline leading into a plain wooden structure measuring twenty by twenty four feet and extending some forty-five feet into the air. This building is the primitive grain elevator, known as the "receiving house." He has no sooner halted his wagon than the fore wheels are raised and the hinder ones depressed, so that his load falls through a trap door into a cleaner, where the wheat is relieved of foreign matter—leaves, bits of straw, twigs, etc.—and then is emptied into the boot of an elevator leg. The leg, which is essentially the same for all elevators, large or small, consists of an endless rubber belt running over two pulleys, one in the boot at the bottom, and the other in the head Upon the belt are fastened at regular intervals small metal cups facing in the direction in which the belt travels. As the pulleys revolve, the cups scoop up the grain from the boot, carry it to the head, and as the cups are inverted in passing over the strap pulley, empty it into a spout placed there to receive it The legs of these small country elevators can lift a thousand bushels an hour, the legs in the huge elevators at Chicago, Buffalo, or other great elevator centers, can lift as much as ten thousand bushels an hour As the grain is delivered from the head of the elevator, it descends through wooden spouts into four grain bins from ten to twelve feet in depth, which form the main part of the building.

The next step is to load the wheat into the freight cars, which are shunted upon a siding adjoining the elevator The operation is simple The grain is drawn from the bottom of the bin into the boot of the elevator, lifted to the top of the house, weighed in hoppers, and then allowed to flow by gravity through a spout into the cars These are the essential operations of all grain elevators, big or small, whether the building is built to accommodate five thousand bushels or two millions From the receiving house the cars are hauled to one of our great Middle West cities, such as Kansas City, St. Louis, or, as would probably be the case, Chicago. In conjunction with other trainloads of wheat they will finally be rolled alongside of, or into a covered way beneath, a huge structure 300 to 500 feet in length, 250 to 400 feet in width, and towering 150 feet



SPOUTS FOR DISTRIBUTING GRAIN TO THE BINS.

into the air. If it be one of the older buildings of its kind, it will be built of timber, but if it be of the latest construction, such as that shown in our illustration of the 2,000,000-bushel elevator for the Grand Trunk Railway at Tiffen, Ontario, or the Santa Fé elevator at Chicago, Ill., of 1,500,000 bushels capacity, it will be built of brick, or tile, or reinforced concrete, this last being the material employed in the two elevators referred to. An elevator of this character is actually a huge warehouse for grain, which is designated by a registered title, is inspected and licensed by the State, and is under the close supervision of the city Board of Trade. Before admission into its bins the grain must be carefully weighed and classified, and when it has once been placed there, the warehouse receipt becomes to all intents and purposes in the money market, the grain itself. It is as easy to deal in it in the market as it is to transfer money in a bank from one account to another. Although the length of time that the five thousand bushels which once filled the little receiving elevator will lie in these bins at the great warehouse depends upon circumstances, the period of its sojourn is a very restless one—restless not for the grain itself, but for that negotiable slip of paper which stands for its sign manual in the market. This may journey hither and thither from seller to buyer until in a short space of time it may happen that our five thousand bushels have been sold and bought, and sold yet again, and that by the mere flick of a man's finger.

Arrived at the great city elevator, the car doors are rolled back and our five thousand bushels of grain are immediately attacked by what is known as the "power shovel." This consists of a large two-handled scoop, to which is attached a rope that is wound upon a rotating drum.

The drum is so fixed upon its shaft that when the man at the shovel walks away with the latter the drum readily unwinds, but as soon as he stops the drum commences winding up the rope and hauls the scoop back to the point at which it started. There are a pair of these shovelers to each car, and they carry the scoop back, bury it in the wheat and guide it as it is pulled forward out of the door of the car and discharges its contents into a hopper that leads to the boot of a huge elevator leg. Two of these shovelers can unload from the cars thirty thousand bushels of grain in a single day.

Now although we have stated that the little receiving house contains all the essential principles of construction and operation of the big city elevator, the likeness is only a general one. The latter are enormous affairs, the greater part of whose bulk is taken up by the grain bins. These in the older elevators were always square in section and some sixty feet in depth. A typical one of this kind is one belonging to the Armour Elevator Company at Chicago, which receives grain from the Milwaukee road. It is 550 feet in length and 156 feet high. It can unload 500 cars of wheat per day and can deliver 100,000 bush

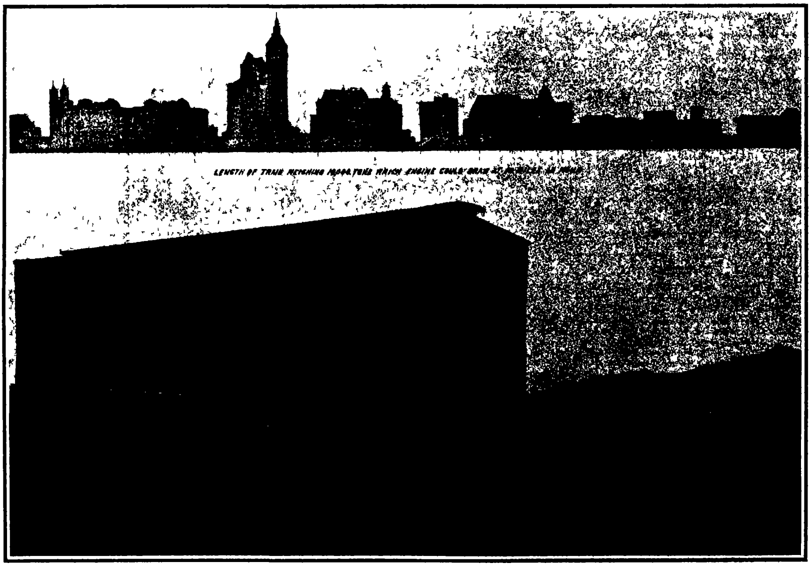
Chicago and the Railroad System of the Middle West.

THE CAPITAL OF THE MIDDLE WEST.—When the first American settler John Kinzie, the Indian trader established himself at the mouth of the Chicago River in the year 1803, he little imagined that he was responsible for the beginnings of one of the greatest cities in the world, nor did he know that he had accidentally hit upon the very spot which by virtue of its geographical location was destined to become the greatest railroad center in the world On the other hand to do justice to this first settler it should be mentioned that the spot which he chose for the home of himself and family was a center even at that early day well adapted for such trade as came his way, for as far back as the early days of French exploration, the Chicago river formed part of a line of travel by which the Indians reached the Mississippi River By journeying up the river and its south branch a portage of some four or five miles brought the Indians across the divide and enabled them to launch their canoes on the Des Plaines River down which they could pass to the Illinois River and so to the great Mississippi It is interesting to note in this connection that the Chicago Drainage Canal a splendid waterway 22 feet deep and from 110 to 202 feet wide follows approximately this old Indian trading route

Whether or no John Kinzie had any conception of the great strategical importance of the place which he had selected to make his home and drive his bargains subsequent history has shown that this lonely spot in the remote wilderness was destined to become the greatest meeting and distribution point of that wonderful network of railways which has grown up so rapidly over the whole face of the United States On the opposite bank of the river from the Kinzie home the United States government located Fort Dearborn a mere stockade containing two blockhouses the first garrison of which consisted of one company of infantry of the First Regiment The settlement at Fort Dearborn made but little growth until after the war of 1812 and in 1830 it consisted of a hamlet of log houses tenanted by less than one hundred people In 1827 Congress authorized the construction of the Illinois and Michigan Canal, and the State was granted alternate sections of land on both sides of the canal route The commissioners proceeded to lay out towns, one of which was Chicago, which was located at the eastern terminus of the canal. The lands were thrown open for purchase in the year 1830 Buildings were erected, and a movement of settlers at once commenced, chiefly by way of the lakes and largely from New York and the New England States. In 1833 Congress made an appropriation for a harbor at Chicago, a channel was cut through the sandbar at its mouth, and in 1834, for the first time, a schooner sailed up the river Three years later the town was incorporated as a city with a population of 4 170

The canal failed to fulfill the high hopes with which it had been constructed, and indeed it was not finally completed until the year 1848, but a new method of transportation was at hand which was destined to do for Chicago and the surrounding country all and far more than had ever been promised by the canal In the year 1847 the first mile of railroad (running toward Galena, Ill) was commenced, and three years later there were forty two miles of connecting lines. In February of 1852 the city was connected with the East by the Michigan Southern Railway, and in the following May by the Michigan Central The effect upon the growth of population was instantaneous. Although between 1837, the year of its incorporation, and 1840 the city had increased only from 4 170 to 4,479 in population, the inception of railroad construction proved such a powerful stimulus that by 1850 Chicago had a population of 28,269, by 1860, of 109 206, and by 1870, of 306 605 Then, in 1871 came the Great Fire That terrible disaster, by all the logic of human events should have dealt a death blow to the city or at least have retarded its growth for many a decade to come. Three and a third square miles of the city were swept out of existence and property valued at $187,000,000 was destroyed, but so far from checking the growth of Chicago the disaster served merely to demonstrate the latent resources of the city, and the unbounded faith both of its people and the country at large in its future destiny The wreck of the wooden city was quickly swept away, and within two years the burned area was covered with buildings of the most modern type, furthermore, nine years after the disaster Chicago had passed the half million mark with a population of 503,298. In the next ten years, the population had more than doubled, the census of 1890 showing 1,099,850. In 1900 it had grown to 1,698,575 souls; and the city's area, which in 1837, the year of its incorporation, was 2 55 square miles, had increased to 190 638 square miles. To-day the population of Chicago is estimated to be 2,573,900, and the assessed valuation of all taxable property is $477,921,976

CHICAGO THE GREATEST RAILROAD CENTER IN THE WORLD.—It takes but a look at the railroad map of the United States to understand why Chicago is to-day, and has been for many years, the greatest railroad center in any country Situated at the southern end of Lake Michigan, which projects far down into the great empire of the Middle West, it not only intercepts all the great trunk railroads, which reach with their connections from the Atlantic to the Pacific, but it forms a natural meeting and transfer point for those products of the West, which seek the advantage of water transportation to and from the East afforded by the chain of Great Lakes In the opening up of the vast unoccupied regions of the West and Middle West, Chicago, in common with St. Louis, formed a natural starting point for the pioneers and immigrants who were seeking to better their fortunes in a new and undeveloped country In this work of development, the railroad was always the predominant factor Starting from Chicago, lines began to radiate out over the wide and fruitful areas of the great Mississippi Valley, across the vast prairies, which awaited only the plowshare and the husbandman to develop their latent fertility, and into the far-distant Rockies, where lay hidden a vast store of mineral wealth. On the other hand, the eastern railroads, as they pushed their way across the range of mountains which separates the older eastern States from the great Middle West, naturally laid their course for Chicago as the natural point of connection with the rapidly extending railroad systems of the West. Meanwhile, the discovery of gold in California, and the increasing enlightenment as to the natural resources in timber and agricultural land of the country lying between the Rocky Mountains and the Pacific coast, had led to an extensive immigration by sea and overland into that country Railroads were built upon the Pacific coast; and it was not long before the systems of the Middle West began to push boldly through the Rocky Mountain range, with a view to securing transcontinental connections. The completion of the first road of this character, the Union Pacific, was



LENGTH OF TRAIN WEIGHING 10000 TONS WHICH ENGINE COULD DRAW

This huge Baldwin freight engine, weighing 300 tons, was built for the Southern Pacific Railroad. It is capable of hauling at 10 miles an hour a train of 130 cars weighing, with load, 78 tons each The train, weighing 10,000 tons, would reach for over a mile or say from City Hall Square to the Battery New York The lower cut represents the size of a single car, 300 feet by 45¼ feet by 60 feet, that would be necessary to contain the load of wheat handled.

THE MOST POWERFUL FREIGHT ENGINE AND THE LOAD IT CAN HAUL.

lowed by the building of the Northern Pacific, the Atchison & Santa Fé, the Great Northern, and this year the Chicago, Milwaukee & St. Paul completed its transcontinental connection. Meanwhile, a great north-and-south route was being built in the Mississippi Valley, which ultimately developed into the present Illinois Central Railway, by which direct communication is afforded from Chicago to the Gulf.

It is impossible within the limits of the present article to enter into the history of the development and growth of the complicated network of railroads which is directly tributary to Chicago, but the claim of the city to be the leading railroad center is suggested by the following table, which gives the number of through and suburban trains into and out of Chicago and the name and mileage of the various tributary roads. It will be seen that out of a total mileage of about 225,000 miles of the whole of the United States, nearly one-half, or 100,123 miles, is directly tributary to the city, and that, over these roads, a total of 1 294 trains enter and leave the city daily

RAILWAYS TRIBUTARY TO CHICAGO

Number of Trains In and Out of Chicago.		Name of Railway	Mileage.
Thro.	Sub-urban.		
19		Atchison, Topeka & Santa Fé	9 976
10		Baltimore & Ohio	4,447
29		Chicago & Alton	998
37	76	Chicago, Burlington & Quincy	8 950
84	206	Chicago & Northwestern Line	9,665

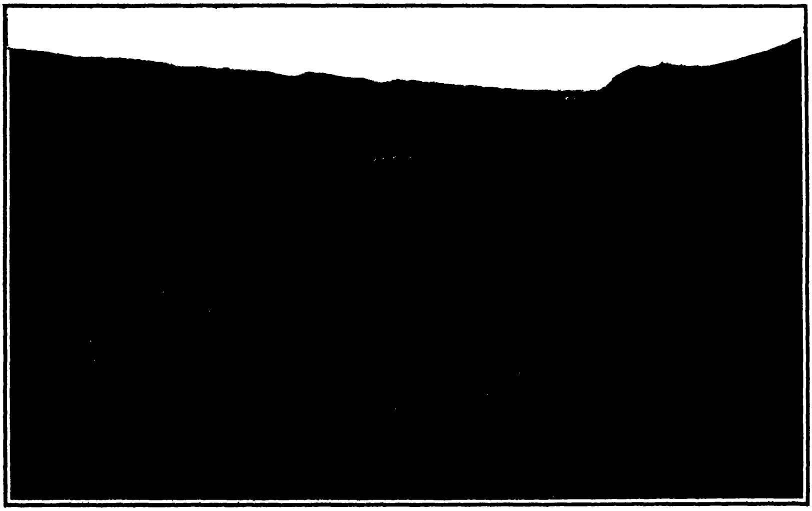
16		Pan Handle Route	
8		Pere Marquette	2,318
22		Wabash Railroad	2,514
541	754		100,123



This line, the latest to be constructed to the coast, is 2,175 miles in length, was built within the brief space of 36 months.

Bridge across the Missouri River at Lombard, Montana.

THE EXTENSION OF THE C., M. & ST. P. RAILROAD TO THE PACIFIC COAST.

Receiving and Distributing the Freight—Elsewhere in the present issue we have spoken of the productiveness of that great empire of the Middle West of which Chicago is the capital Spread out over the twelve States, which in government reports are known as the North Central Division of the United States, with their area of 753,550 square miles, and their population of over 30,000 000, are between 85 000 and 90,000 miles of track Within this area is more than one-half of the wealth invested in improved farms in the United States, and over one-half of the live stock and neat cattle It produces 78 per cent of the total food products and more than one-half of the butter cereals, potatoes, and poultry that are raised in the entire country Although distinctly an agricultural district, it is rapidly moving forward to its ultimate position as the leading manufacturing center Already it possesses 190,000 manufacturing establishments representing an invested capital of over $3 000 000 000 which pay out annually between $700,000,000 and $800 000 000 in wages, and the value of whose annual products is about $4,500 000,000, or about 35 per cent of the value of the products of the whole country As far back as 1905, the total output of bituminous coal was 81 000 000 tons, or over 32 per cent of the total amount of bituminous coal mined in the United States That Chicago is the center to which the products of the West and Middle West are carried for distribution and reshipment is shown by the statistics of the Chicago Board of Trade for 1908, from which we learn that in that year the railroads brought into the city over 10 000 000 barrels of flour and 239 000 000 bushels of wheat corn oats, rye, and barley of which over 9,000 000 barrels of flour and over 180 000,000 bushels of cereals were reshipped by lake and railway In the same year over 3,000,000 cattle and 8,652,000 hogs were received at the stockyards by rail. Of potatoes over 12 500,000 bushels, and of hay some 300,000 tons were brought in, mainly by rail Limits of space prevent any further statement of statistics, but enough has been quoted to give an adequate impression of the enormous quantity of freight which day by day enters the city either for home consumption or for reshipment to other ports

Chicago has solved the problem of redistribution and reshipment admirably by the construction of a belt railroad, which extends around the city, and connects with each of the railroad freight terminals. As the trains roll into the various yards, they are broken up, and the various cars sorted out and rearranged according to the particular railroad over which their journey is to be continued, or the particular point within the city at which delivery is to be made. The resorting of the cars is done in some cases by gravity, the cars being started down a gentle incline, at the bottom of which the track communicates by switches with scores of parallel tracks, on which the separate trains are made up This railroad is a complete organization in itself, possessing its own locomotives, train hands, and office staff, and the system of distribution is probably the most efficient of its kind in the world In this connection it is interesting to note that within the limits of the city of Chicago are more miles of railroad track than some States contain within their borders Altogether 2,494 59 miles of track are owned by eighteen of the twenty-six lines which center in Chicago

Chicago's Sixty Miles of Freight Subway—The Illinois Tunnel Company owns and operates sixty miles of subway for freight traffic under the business heart of Chicago Connections are made with all of the principal freight and passenger stations of the city and with the docks on the three branches of the Chicago River There are also connections with the basements of many of the leading wholesale retail and manufacturing industries of Chicago A disposal station is situated on the west bank of the Chicago River from which vast quantities of excavated material refuse and other waste are loaded on scows and transported to final dumping grounds away from the city The direct connection of the freight subway and this disposal station saves hauling through the streets of Chicago thousands of tons of waste material The tonnage of freight handled to and from the railways through the tunnel has shown a steady increase during the last six years, and has decreased the hauling by teams through the city Whether the bore of this tunnel will be enlarged to accommodate passenger traffic as well as freight traffic is one of the problems now under consideration, but it seems reasonable to expect that a start will be made in the near future on some plan to handle the immense passenger business within the city underground and thereby relieve the congestion of the streets

Railway Terminal Facilities—Until recently the terminal facilities for passenger service in Chicago have not been commensurate either with the importance of the city or with the size of its passenger traffic This condition, however, is being fully corrected The president of the Pennsylvania Railroad recently announced that a new station would be built in Chicago, and that the work would be started at an early date and pushed to completion as rapidly as possible The cost of the new Union Station is to be about $25,000 000, and it will be occupied by the same railroads that now use the Union Station the Pennsylvania, the Chicago, Milwaukee & St Paul the Chicago & Alton, and the Chicago, Burlington & Quincy

The Northwestern Railway is completing a $20,000,

(*Continued on page 453*)

IRON THAT WILL NOT RUST.

In 1856 Sir Henry Bessemer invented a process of steel making which revolutionized the iron and steel business. By this method it was possible to turn out an immense tonnage at a low cost and with a low percentage of carbon and manganese. To be able to produce in large quantities and at a low cost a metal which had even greater tensile strength and ductility than good iron at once enabled steel to take the place in commerce hitherto held by iron.

While steel had a greater tensile strength and greater rigidity than iron it had certain limitations which have grown increasingly apparent. These limitations appear in the use of steel where it is subject to severe corrosive agents, as for example in the atmosphere of cities impregnated by the fumes of gas or coal smoke, at the seashore with its salt air, in the ground with its dampness, or in localities where it becomes the intermittent conductor of electrical currents. Steel has come to be considered under these conditions and notwithstanding its extreme hardness of texture a comparatively short lived metal.

Iron nails taken from demolished houses that were built in the eighteenth century are handed about as curios for to-day. In many a shingled roof the shingles outlast the steel nails. The Department of Agriculture voiced the sentiments of the farmer when it urged upon wire makers the necessity of improving the character of the wire fence so that the farmer using it would not have to renew it every five to nine years. The thrifty housewife pleased with the beauty and strength of her new galvanized water pail, is surprised and indignant at having her maid call her attention, as it seems to her after a very short time, to the holes in the bottom.

It is generally considered a plausible if not demonstrated theory that this fugitive nature of steel comes from its chemical structure. The elements introduced into the molten mass of iron in the furnace and in the ladle to convert iron into steel are essentially impurities. Under certain conditions an electrolytic action is set up within the structure of the steel between these impurities with a resultant disintegration of the metal.

There is a growing conviction that the corrosion of metals is due to this electrolytic action. According to the latest theory rusting commences on the surface of the metal because of a difference of potential there, a condition which is due to the impurities in the metal such as carbon, sulphur, phosphorus and particularly manganese. Dr. A. S. Cushman in a pamphlet entitled "The Corrosion of Fence Wire," published by the United States Department of Agriculture, arrived at the conclusion that steel corroded more rapidly than iron for several reasons, chief among which were the following.

First. The presence of and the irregular distribution of manganese in steel, there being little if any of that substance present in iron.

Second. The greater destruction of steel by electrolysis as compared with iron, due to the presence of manganese and various metalloids in greater quantities than in iron.

Third. The absence of slag in steel, whereas the slag distributed throughout iron was believed to act as a rust preventive.

The same authority says: "If we accept the electro-chemical explanation of the corrosion of iron, there can be no doubt that conditions which inhibit electrolytic effects also inhibit corrosion and *vice versa*. The purer the iron in respect to certain metals which differ electro-chemically from iron and the more carefully the lack of homogeneity and bad segregation are guarded against, the less likely are the electrolytic effects to become serious. These points constitute the essential problems which confront the manufacturer who desires metal that will have a high resistance to corrosion."

A few years ago the American Rolling Mill Company, of Middletown, Ohio, began to investigate the possibility of producing from their open hearth furnaces from which they were making high-grade steel by the usual method, a steel very low in carbon and manganese. The success achieved in this direction suggested that it might be possible to reduce the scrap and pig iron to a molten mass in an open hearth furnace and cast it into ingot iron without introducing the impurities that are known to be active agents in corrosion.

In making steel by the open hearth process, the furnace is charged with many tons of selected scrap and pig iron and the charge is raised to a sufficient temperature to burn out the carbon and the greater part of the other impurities. When these have been reduced to the desired extent a predetermined amount of carbon and in particular grades of steel of other ingredients is added to the molten metal until its composition has been brought to the exact point called for by the specifications for the particular grade of steel which is being made. In the experimental work of the company above referred to the treatment was entirely one of elimination, the effort being to get rid of practically the whole of the impurities, and bring the metal as nearly as possible to the condition of absolutely pure iron. They carried the process of burning out the impurities even further than is done in the manufacture of commercial steel, and there the process stopped, leaving in the bath a remarkably pure iron which was subsequently cast into ingots and was available for use in the rolling mills and elsewhere for manufacture into commercial products.

An analysis of this iron in comparison with commercial steel, as made by William M. McPherson, professor of metallurgy, Ohio State University, Columbus, Ohio, showed the following results:

	Steel	American Ingot Iron
Sulphur	0 048 per cent	0 021 per cent
Phosphorus	0 094 per cent	0 005 per cent
Carbon	0 11 per cent	0 02 per cent
Manganese	0 47 per cent	Trace
Silicon	Trace	Trace

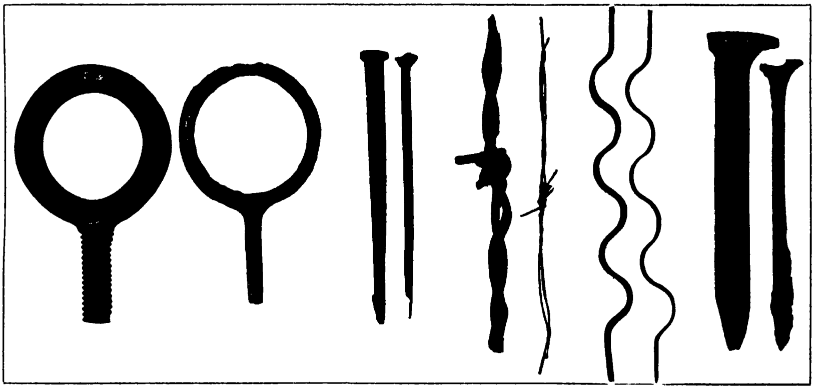
The corrosion test of the above samples, which were immersed in a 5 per cent solution of sulphuric acid for twenty four days, showed:

Loss, steel	14 41 per cent
Loss, American ingot iron	0 31 per cent

"The above material," says the report, "is very exceptional for its purity, and is the most non-corrosive material that I have examined."

Four specimens of ingot iron subjected to tests to determine its tensile strain showed the following results: Breaking strain per square inch, from 49,857 pounds to 51,905 pounds, limit of elasticity per square inch, from 35,395 pounds to 41,377 pounds, elongation per cent of length, from 40 per cent to 48 per cent.

We present a set of comparative illustrations, showing the results of corrosion tests on various articles of commerce, one of each pair being made of the new ingot iron, and the other of steel or other material. In every case, both specimens were immersed in a bath of 25 per cent sulphuric acid. The ingot iron and charcoal eyebolts were treated in the bath for six hours, at the end of which time the ingot iron eyebolt showed a loss of 15 5 per cent, and the charcoal iron eyebolt a loss of 77 3 per cent. In a five-hour test of two railroad spikes, the ingot iron specimen lost 11 2 per cent, and the steel spike 79 1 per cent. Even more remarkable was the comparison of ingot-iron and barbed-wire fencing material, the steel wire losing 92.8 per cent at the end of one and a half hours, and the ingot-iron wire losing only 6 1 per cent. In a forty five minutes' test of two nails, the steel nail lost 68.9 per cent, and the ingot iron nail 4 13 per cent. The two specimens of corrugated roofing material were placed in the bath for fifty minutes, at the end of which time the steel specimen had lost 78.2 per cent, and the ingot iron 2 4 per cent.



Ingot Iron Loss, 15.5%.   Charcoal Loss, 77.3%.   Ingot Iron Loss, 4 13%. Steel Loss, 68.9%   Ingot Iron Loss, 6.1%. Steel Loss, 92.8%.   Ingot Iron Loss, 2 4% Steel Loss, 78.2%.   Ingot Iron Loss, 11.2%, Steel. Loss, 71 9%.

CORROSION TESTS IN BATH OF 25 PER CENT SULPHURIC ACID

◆

CHICAGO'S SIXTY MILES OF FREIGHT SUBWAY.

In our Engineering Number of December 5th of last year we illustrated a system of freight subway which had been proposed for solving the serious problem of freight congestion on the streets of this city. In the present Middle West Number we present illustrations of a complete system of freight tunnels, aggregating sixty miles in length, which has been completed below the business center of Chicago, and is now regularly engaged in conveying merchandise and the city's mail directly to and from the railways, the Post Office, and the various office and commercial buildings of the city. The Chicago freight tunnels stand as a unique achievement among the great municipal undertakings of the world, and the capital city of the Middle West very justly prides itself upon the magnitude and completeness of this constructive work, which ranks in importance with that other great Chicago enterprise, the Drainage Canal.

The underlying conditions which have led to the construction of the subway are the same as those that have prompted two powerful construction companies to make an offer to build a similar freight subway system beneath New York city, namely, the intolerably congested condition of the street traffic. It is the slow moving and bulky dray and the various freight and express vehicles that are chiefly responsible for the growing street congestion in the business centers of our great cities. It is claimed that, before the construction of its tunnel system, the conditions in the heart of Chicago were worse than in any other city,

A Modern Factory Building with WROUGHT STEEL "DETROIT FENESTRA" WINDOWS

TO ARCHITECTS AND ENGINEERS We are now ready to place on the market four complete types of standard sash in

Wrought Steel "Detroit Fenestra"

viz

Type "A" in 21 sizes and degrees of ventilation, 10" x 16" glass
Type "B" in 21 sizes and degrees of ventilation, 12" x 18" glass
Type "C" in 6 sizes, 12" x 18" glass, large ventilation
Type "M" in 2 sizes, 12" x 18" Ventilated Monitor Sash

All these standards are made as interchangeable units, and mullions are supplied where they are to be used in combination

Immediate shipments are insured when openings are planned to take standards

Send for our new pamphlet "Y," containing full details and dimensions of these standards, with instructions for erecting and glazing

FOR FACTORIES, WAREHOUSES, MILLS, CAR SHOPS, POWER STATIONS, GARAGES, INSTITUTIONS AND ALL INDUSTRIAL BUILDINGS

RECENT INSTALLATIONS OF THIS MATERIAL:

Indiana Steel Co. (U S Steel Corporation) Gary Ind.
Jenks & Muir Mfg Co., Detroit, Mich
Reinforced Concrete Pipe Co., Detroit, Mich.
Allyne Brass Foundry Co., Cleveland Ohio.

THE WONDERFUL IRON MINES OF LAKE SUPERIOR.

(*Continued from page 431*)

the Panama Canal as the greatest task of its kind ever undertaken, yet it is a fact that at the close of the present year the stripping of the surface material and the excavation of the ore from the Mesabi range alone during the seventeen years that mining has been carried on will represent a total of excavation equal to that required for the Panama Canal

TRANSPORTATION OF THE ORE.—Apart from the easy accessibility of the ores, particularly in the Mesabi range, the low cost at which the iron ore is delivered to the railroad cars or on the stock pile at the Lake Erie ports is due in a large measure to the present system of mechanical handling and transportation which enables a huge tonnage to be moved in a minimum of time and for a minimum of cost. From the time the ore is lifted by the shovel in the "open pit" mine, or is loaded into the skip of the deep underground mine, it is handled entirely by mechanical means and no human hand comes in contact with it. The trains of ore cars, as they arrive at the Lake Superior ports, are run out directly above long elevated docks, consisting of continuous rows of ore bins. The hinged bottoms of the cars are released and the loads dropped into the ore pockets, where the material remains until the ships steam alongside for loading. Hinged to the bottom of the ore pockets are long rows of metal chutes, and as a chute is lowered into position over the hatch of the steamship, the gate at the bottom of the ore pocket is opened, and the ore slides by gravity into the hold. The ore-shipping piers of the Great Northern Railway at Superior are capable of receiving and loading from five to six million tons of ore in a season, and they have a record of loading a ship of 5,250 gross tons in 30½ minutes. An even greater feat was the loading of the steamer "H E Corey," of 10,000 tons capacity at Duluth and Iron Range steel ore dock at Two Harbors, Minn., this season, in 39 minutes. One of the piers of the Great Northern Railway Company is 73 feet above water level 62½ feet wide, nearly half a mile in length, and has a storage capacity for 87,500 tons. The construction of a special type of ship of large tonnage for the ore trade coupled with the invention of unloading machinery of great capacity at the terminal ports, has brought the cost of transportation down to a very low figure Thus, a ton of ore is now hauled one hundred miles by rail from the most distant mines in the Lake Superior range to a Lake Superior port is loaded into the ship, is carried one thousand miles by water and unloaded into cars or onto the stock pile at a Lake Erie port, at a cost of less than $1.80 per ton

The iron-ore steamer of the Great Lakes has been designed with a strict reference to the economical loading, transportation and unloading of iron ore in bulk Its characteristics are great length, moderate draft, and a huge cargo hold which extends continuously for nearly the whole length of the vessel, and is provided with a continuous row of hatches extending the full length of the hold We present an inboard profile and a cross section of the "Wolvin," one of the largest of the typical ore steamers This vessel is 560 feet in length, 56 feet beam, and 32 feet deep The cargo hold is built in the form of a long hopper whose sides slope from the main deck to the top of the ballast tank. The hopper is 48 feet wide at the top 24 feet wide at the bottom, and extends continuously for a length of 409 feet The space between the hopper and the outside of the vessel forms two series of water-ballast tanks, the ballast space being divided into compartments by athwartship bulkheads built in at intervals of 60 feet. The tanks have a maximum capacity of 8 000 tons of water Transverse stiffness is afforded to the sides of the vessel by a system of arched girders, which also serve to support the upper deck and the hatch covers Between the girders are 33 hatches, each of which measures 9 feet by 33 feet in the clear The largest single cargo of ore carried by the Wolvin was 11 536 tons, a feat which she performed in 1904 The pilot house bridge and captain's quarters are forward at the bow Aft of the cargo space are the coal bunkers boiler room engine room, and the quarters for the crew

Great as are the dimensions of the 'Wolvin they have been exceeded regularly in each succeeding year The E H Gary' in 1905 carried a single cargo of 12,368 tons in 1906 the J P Morgan' carried a single cargo of 13 272 tons of ore and in 1907 she carried 13 800 tons Equally remarkable for size are some of the sailing cargo ships the most notable of which is the John Smith which in 1907 carried a single cargo of 9,408 tons.

It is the magnitude of the ore trade which has made the Sault Ste Marie canal the most important artificial waterway in the world at least in respect of the bulk of tonnage passed through According to figures given at the thirteenth annual meeting of the Lake Superior Mining Institute, the maximum freight traffic through the canals for a single day was on August 26th 1907 when 487 000 tons were passed through in 121 vessels The total traffic into and out of Lake Superior for that year was 58 217 214 tons, on which $38 458,345 were paid as freight charges. Of this total tonnage 68 per cent was iron ore

UNLOADING AND HANDLING MACHINERY.—In order to keep pace with the low cost and speed with which the huge bulk of iron ore is mined, loaded into special steamers, and carried to its destination at the various Lake Erie ports it was necessary to design special unloading machinery capable of lifting the ore from vessels and loading it either into the stock pile or into railroad cars with proportionate speed and at a relatively small cost per ton The design and construction of this class of machinery has grown to such importance that there are several large industrial concerns which are occupied almost entirely with this class of work In one of our views illustrating the interior of the hold of the Wolvin and also in the general panoramic view of the water front of the Gary Steel Works we show what is known as a Hulett automatic ore unloader Four of these machines located at the docks at Conneaut Ohio are credited with having taken out of the Wolvin 7 257 gross tons of ore in four and one half hours At present there are five of the Hulett unloaders at Gary and when the plant is completed there will be ten The plant consists of a massive walking beam to the outer end of which is pivoted a vertical arm At the bottom of the arm is a bucket capable of lifting ten tons at each operation As the bucket descends into the hold of the vessel the two halves open and are automatically moved apart in a horizontal direction so as to make a wide grab of the ore The machines at Gary are carried on two tracks 62 feet apart and span two railroad tracks laid parallel to the edge of the dock They are operated by electricity and each weighs about 450 tons and requires only three men for its operation They are showing a capacity for unloading ore at an average rate of 300 tons per hour for each machine As each bucket load is lifted it delivers the ore to a conveyor car which travels back to the rear of the machine and discharges its load into suitable hoppers at the rear

PITTSBURG, PA.

to present photographic views of several types of unloading machinery as installed for the unloading of iron ore coal and other heavy materials in bulk at various ports on the Great Lakes During the recent meeting in New York of the Society of Naval Architects and Marine Engineers a paper was read on Material Handling Equipments for Lake Vessels which traced the development of this type of machinery from the year 1880 At that time dock managers were looking for some mechanical means for lifting the ore from the ship and depositing it at some distance from the face of the dock, and this was first accomplished by a cableway machine, built and erected at Cleveland in 1880 under Mr Alex E Brown s supervision From that first device have been developed the mammoth machines of the Brown hoist type They consist essentially of a long overhead bridge extending at right angles with the dock and supported on two towers, one at the dock the other 200 to 300 feet inshore Upon the bridge are rails, on which travels a self propelled trolley Upon the trolley are motors for hoisting the load and for moving the trolley to and fro upon the bridge In unloading the trolley runs out over the hold, the grab bucket descends and grabs its 5 to 7 tons of ore, raises it and then the trolley travels back to the stock pile, where the load is dropped

◆

GARY THE LARGEST AND MOST MODERN STEEL WORKS IN EXISTENCE

(*Continued from page 441*)

purified has an average heat value of 95 British thermal units per cubic foot

It is estimated that 2¼ times as much power can be derived from a given quantity of gas with gas engines as with boilers and steam engines

THE OPEN HEARTH FURNACES

The hot metal is tapped from the bottom of the furnaces into 40-ton ladles, mounted on massive eight wheeled trucks, which are hauled successively beneath the pouring spout When a train of ladles is made up it is hauled to the mixer building, which contains two huge receptacles each of 300 tons capacity Into these the ladles discharge the hot metal, and the mixing of the product of the different furnaces insures a uniform average of composition of the metal From the mixers which are arranged so that they can be rocked or tilted, the molten metal is poured into 60-ton charging ladles which are conveyed to the charging side of the open hearth furnaces on electric transfer cars From these cars the ladles are picked up by a 75 ton traveling crane and the metal is poured into the open hearth furnaces through a runner

The whole of the output of the Gary plant consists of open hearth steel and the open hearth furnace plant is by far the largest of its kind in the world It is housed in large steel-frame buildings 193 feet in width and 1 190 feet long Ultimately there will be six of these buildings each containing fourteen 60-ton furnaces, or eighty four furnaces in all To the molten metal with which each furnace is charged there is added a certain amount of steel scrap, and the charge is then subjected to the fierce heat of burning gases which enter at one end of the furnace pass over the charge, and leave through flues at the other end From time to time samples are taken from the furnace and tested The object of this treatment is the same as that of the air blast in the Bessemer converter, and though the operation consumes more time the product is very much more reliable The impurities are burned out of the metal until the proper percentage of carbon, etc for the particular grade of steel which is being made has been reached. The metal is now ready for pouring.

Down each side of the long line of open hearth furnaces is a set of railroad tracks on which the metal is brought to or removed from the furnaces, and handled thereat. On the tapping side on which the treated metal is withdrawn from the furnaces is a line of massive standards in which are placed the ladles of 80 to 100 tons capacity into which the metal is poured When they are full, the proper amount of ferro-manganese is added to the metal in each ladle, and they are then picked up by 125-ton traveling cranes and carried to platforms from which, by opening a plug in the bottom, the molten steel is poured into the ingot molds large cast iron molds 65 inches in height tapering from 20 by 24 inches at the bottom to 18¾ by 22¾ inches at the top Here the metal cools to the point of solidification. The mold is then lifted off the ingots which by the way, are carried on four wheeled cars, each car carrying four molds, and after having been heated to a uniform heat throughout in the 'soaking pits' the product is ready for rolling in the billet mill or the rail mill

It should be mentioned that in order to take care of the product of the blast furnaces on Sundays and holidays, when the open hearth furnaces are not at work, the hot metal is brought in ladles to the casting machine, where it is poured into an endless chain of traveling molds which passes continuously below the mouth of the ladle. There will be eleven of these machines for the service of the complete plant

BILLET MILL.

Standing parallel with the rail mill is an electrically operated billet mill, in which a portion of the ingots are rolled down to suitable size for further manipulation throughout the plant Here are four 40-inch blooming mill stands, each pair driven by a 2,000-horse-power electric motor, and a five-stand continuous 32-inch mill driven by a 6,000-horse-power motor Beyond this are two blooming shears, 12 x 12 inches and 10 x 10 inches. Next the blooms go to a 24-inch 6-stand continuous mill, driven by a 6,000-horse-power motor, or to a pair of cooling beds for shipment If further reduction is desired the billet is sent to a 6-stand 18 inch continuous mill and rolled down to sizes varying from 3⅛ inches square to 1⅜ inches square

LARGEST RAIL MILL IN THE WORLD

The Gary plant contains the largest rail mill in existence It is also the only electrically driven mill which rolls rails direct from the ingot without reheating. The proportions are immense, the main building being 990 feet long by 76 feet wide, with another building containing the soaking pits, for both rail mill and billet mill which is 1,350 feet long by 84 feet wide The soaking pits are square chambers with hydraulically operated sliding doors in the roof, capable each of holding four 4-ton ingots They are heated by gas and in them the ingot is brought up to the proper temperature for rolling The roll trains are driven by six 6,600-volt induction motors, three of 6 600-horse-power and three of 2,000-horse-power The finished rails are taken to inspection beds in a finishing department and are then loaded on the cars. This rail mill can turn out 4,000 tons of 80-pound rails in twenty-four hours.

GAS-ENGINE-OPERATED BLOWER PLANT

Air blast for the furnaces is produced in two buildings, 550 and 600 feet long and 104 feet wide, which are among the most interesting features of the Gary plant. The blowers, of which there are twenty in all, are driven by sixteen gas engines and four steam engines. These blowing engines are of great size and power. The gas and blowing cylinders are placed in tandem. The gas cylinders are 42 inches in diameter and the blowing cylinder 72 inches, and they have a common stroke of 54 inches. Each engine is of 2,000 horse-power [illegible] at a speed of 60 revolutions per minute, and each delivers 22,000 cubic feet of free air per minute at a normal pressure of 18 pounds per square inch. The gas engines were built by the Allis-Chalmers Company and the Westinghouse Machine Company. When the plant of sixteen furnaces is completed there will be no less than thirty-two of these engines with a total horse-power of 64,000

GAS-DRIVEN ELECTRIC POWER PLANT

The most interesting feature of the whole establishment at Gary is the huge power house, 105 feet wide and 966 feet long, which provides the electric current for one-half of the complete plant. It is the largest gas-power plant in the world and contains seventeen horizontal twin-tandem double-acting Allis-Chalmers gas engines of 3,500 horse-power, each directly connected to a 2,500-kilowatt generator, fifteen of which are 6,600-volt alternating-current machines and the other two 250-volt direct-current machines. These huge engines are the largest ever constructed for the use of blast furnace gas. Their cylinders are 44 inches in diameter by 54 inches stroke Each twin unit carries on a 30-inch shaft a 23-foot 100-ton fly-wheel. The plant also contains two Curtis steam turbine generators for starting and for auxiliary service in case of necessity Additional gas-electric engines will be provided in two separate buildings, aggregating 60,000 horse-power Thus the ultimate capacity of the electric power plant will be 120,000 horse-power

Limitations of space prevent any more detailed description of the many features of interest which are found at Gary The combined steel plant and city of Gary are the most noticeable instance in America of the rapidity with which a large area of apparently valueless land may, at comparatively short notice, be transformed into a huge center of industrial activity Not only is about one-half of the plant in operation, but the adjoining city already has a population of 15,000 souls. Four years ago the site was a wind-blown waste of sand on the shores of Lake Michigan

---

THE HANDLING AND STORAGE OF OUR HUGE GRAIN CROP

(*Continued from page 445*)

els per hour to cars or boats. It has a rated storage capacity of 2 500,000 bushels, and it may be mentioned here that the elevators of the Armour Company alone are capable of storing 13 500 000 bushels a day This elevator is constructed entirely of wood, and the square bins which range in size from 500 to 7,000 bushels capacity, are built of spruce planks, 2 x 4 inches at the top of the bin and 2 x 10 inches at the bottom laid lengthwise upon each other, and each spiked to the layer below The whole interior of the main body of the building is built up of a perfect honeycomb of these bins. The bottoms are tapered and finished in spouts to insure a free delivery of the grain in unloading

The more modern elevators, such, for instance, as those designed by the Metcalf Company and shown in our illustrations, are built of reinforced concrete, the bins being circular in form, are of great strength, and of thoroughly fireproof construction. The square tower-like building contains the elevating, cleaning, weighing, and conveying machinery At about the middle height of this building horizontal covered passageways serve to contain conveyer belts, by which the cleaned and weighed grain is transferred to the top of the bins and loaded into the particular bin desired.

The annual shipment of grain to Europe is about 150,000,000 bushels, and as our five thousand bushels from the Dakota farm are destined to cross the ocean, we will trace its course from the Chicago elevator in which it is reposing to its final stowage in the hold of an ocean cargo steamer. At the end of its railway journey to Chicago, the grain passes through similar experiences to those it

(*Continued on page 452.*)

THE SOUTHWEST LIMITED TO EXCELSIOR SPRINGS

TAKE THE SOUTHWEST LIMITED to Excelsior Springs, Missouri, and enjoy a visit there now—the most delightful season of the year.

With its improved hotel accommodations Excelsior Springs has become an ideal health resort.

The curative powers of the waters of its various springs have been a great boon to thousands of sufferers from kidney diseases, rheumatism and stomach troubles.

Excelsior Springs is one night's ride from Chicago, on the

Chicago Milwaukee & St. Paul Railway

THE SOUTHWEST LIMITED leaves Union Station, Chicago, 6.00 p m., arrives Excelsior Springs 6.50 a m the next day Returning, leaves Excelsior Springs 7 16 p. m.; arrives Chicago, 8.20 a m

THE SOUTHWEST LIMITED carries electric-lighted compartment, observation and standard sleepers, chair cars, coaches and dining car, serving table d'hote dinner and a la carte breakfast.

NEW BOOKS, ETC.

NELSON'S PERPETUAL LOOSE LEAF ENCYCLOPEDIA Editor in Chief, John H Finley, LL.D., President of the College of the City of New York. Associate Editors, William Peterson LL D, C M G, Principal of McGill University, Montreal, Canada, and George Sandeman, M A., Edinburgh, Scotland New York Thomas Nelson & Sons, 1909 Twelve royal octavo loose-leaf volumes, illustrated with colored plates plans, and engravings

In these days, when history is making so rapidly as to call for daily and even hourly editions of newspapers, and science is advancing at such a pace that new periodicals are constantly cropping up to announce developments in specialized branches the mere task of collecting this mass of material condensing it classifying it sifting out the errors and finally putting it in such a form as to be of value as a record for the well informed man is in itself stupendous but it is disheartening to know as all makers of encyclopedias do know that the very day after publication the work is beginning to grow old and out of date The mass of information which is contained between the covers of an encyclopedia is living material matter that is as alive as the age in which we live Hence it is inconstant Part of it is aging and dying *much of it is* developing and expanding and is giving birth to new ideas and the effort to keep all this material in alphabetical order and keep it abreast of the times has always been a serious problem which *the publication* of annual volumes has not solved for the reason that the additional matter published contains only the new facts while leaving the old and worn out ideas in the original encyclopedia where they are liable to mislead the reader A new departure in this line has just been made in the Nelson Loose Leaf Encyclopedia which is so arranged that any facts which may become out of date can be taken out of the very heart of the volume and replaced with new material without in the least affecting the alphabetical order or destroying the arrangement as a book of ready reference The loose leaf binding is ingeniously contrived to give the volume the appearance of being permanently bound Nelson's Encyclopedia was first prepared in permanent binding in 1907 When a year later the loose-leaf edition was published it was found necessary to make 800 changes in order to bring the encyclopedia up to date A large staff of editors is employed to keep the present encyclopedia up to the hour and from time to time new leaves are issued and sent *to the subscribers furnishing them* with authoritative information on current topics and informing them where to insert the matter in the encyclopedia As an illustration of the up to dateness of this system a set of leaves was issued last month on the death of Governor Johnson and on the Cook Peary controversy These leaves are temporary and in March of each year a complete set of leaves of about 500 will be sent to each subscriber to add to his encyclopedia and to replace matter that is out of date Formerly a man could obtain better information on the occurrences of the previous decade than those of the current year With the advent of Nelson's Encyclopedia such is no longer the case The subjects covered in this work are many probably a greater variety than is to be found in any other encyclopedia of the same number of volumes The articles are therefore short and concise The aim of the encyclopedia appears to be to provide general information and to avoid technical language as far as possible to furnish not merely a record of events but to give instructions wherever possible that will be of practical value to the reader Take for example the entry Cycle Not only is a brief history of the bicycle given but also instructions to the prospective buyer of a wheel which will enable him to choose the best machine and hints on the care of a wheel This strikes us as a rather unique feature but one that will doubtless be appreciated by many subscribers to this work The articles are a trifle more brief than one would like to have them but they are accompanied by carefully selected bibliographies for those who desire to study the subject further The encyclopedia appears to be an exceptionally good gazetteer containing many geographical names that do not appear in other works of this kind A pronouncing dictionary is placed at the end of each volume so that if a person is in doubt as to the pronunciation of a certain word he can look it up very quickly and without having to wade through the body of the book where his attention is liable to be diverted by the many interesting subjects which the volume contains

WILD FLOWERS AND TREES OF COLORADO By Francis Ramaley Ph D Boulder Colo University Book Store 1909 8vo 78 pp

This little volume is intended as an introduction to Colorado plants It is not a result of book study but of many summers work on Alpine heights and on the plains It will prove of interest to all students of botany particularly if they live in the State of Colorado

TABLES AND OTHER DATA FOR ENGINEERS AND OTHER BUSINESS MEN By Charles B Ferris B S Knoxville Tenn Published by the University Press. Price 50 cents

(Continued from page 451.)

had at the receiving house. It is discharged into the boot, carried up the leg, and spouted into the bins. This time, however, instead of one leg, there may be from sixteen to twenty, and the four bins will have increased to over one hundred. Our five thousand bushels of grain then are discharged by gravity from the bottom of the bin to the boot of an elevator, are lifted and discharged again into a big spout, through which they flow directly down into the hold of a lake cargo vessel moored alongside the elevator.

This vessel is of a special type which has been developed for the lake trade. Although she may be capable of carrying over ten thousand tons of cargo, she is nothing more nor less than a huge barge with straight parallel sides, blunt of bow and stern, with accommodations for the seamen at the bow and with engine boilers and captain's accommodations at the stern. The main body of the ship consists of one vast hold, access to which is gained by a long line of hatches. Our 5,000 bushels of grain together with hundreds of thousands of bushels that may have been gathered from half a dozen different centers in the wheat-growing districts of the West, now start on their long journey at ten or twelve knots an hour to Buffalo, being consigned to one of the great waterside elevators in that city. The vessel is moored alongside the elevator, with its hatches opposite a huge tower-like structure built against its side and extending a story higher than the rest of the building. Inside of the tower and swinging from a hinge at its top is a huge steel-and-timber structure, which is nothing more nor less than our old friend the belt elevator grown to Brobdingnagian proportions. Almost before the ship is alongside and the hatch covers are off, this swinging elevator is moved until its boot hangs directly over the opening into the hold. The boot is extended until it enters the hold and is buried deep in the mass of grain. The elevator leg is some 90 feet in length and it can be raised or lowered some 50 feet if necessary. In a single hour it can lift 15,000 bushels out of the hold and into the elevator.

As the grain reaches the head of the tower leg, it is shot directly into a receiving bin. Beneath this bin is a weighing scale with a hopper of 200 bushels capacity. The scales are set for a certain weight, and the weighing hopper is filled by pulling a lever which moves a slide in the bottom of the receiving bin above. The man who does the weighing is so expert that he can fill the scale hopper with the exact amount, no more nor less, once in every fifty seconds, which he must needs do when the huge marine leg is pumping grain out of the hold at the rate of 15,000 bushels per hour. From the weighing hopper the grain is delivered direct to the storage bin, or if, like our 5,000 bushels, it be destined for transportation across the sea, it will be carried across the building and out again as fast as the railway cars can be found to accommodate it. The cars will carry the grain direct to one of the great grain-exporting seaports, Portland, Boston, Newport News, or New York.

The method of operation at the seaport elevators is similar to that of the Chicago warehouse. The main difference is that, whereas at Chicago the barge-steamer lay against the side of the elevator and the grain was delivered directly to the hold through the spout below the open door, it will frequently happen that the grain must be carried several hundred feet out over a pier and there discharged into the hold of the ocean-going steamship. This is done by means of a belt conveyer.

Now, this is not by any means the first time that our consignment of grain has made its acquaintance with the belt conveyer, which has been aptly described as the elevator leg belt stripped of its metal cups and lying upon its side. The belt conveyer is extensively used in the vari

Chicago & North Western Ry.

NEW PASSENGER TERMINAL, CHICAGO—Madison Street Entrance

THE PORTAL OF THE WEST

THE New Passenger Terminal of the Chicago and North Western Railway at Chicago is to be one of the finest monuments ever erected to the commercial life and spirit of the West.

It is to be located between Canal and Clinton Streets, extending from the main entrance fronting on Madison Street, over Washington and Randolph Streets to Lake Street.

More than $20,000,000 is to be expended to provide a railway entrance to the city through which passenger traffic to and from the territory that has made Chicago powerful and rich is to move in ceaseless activity.

Work upon the new station is proceeding with all the rapidity that skill and liberal expenditure can command.

The new station will have a capacity for handling a quarter-million patrons daily.

It is confidently asserted that its provisions for doing this expeditiously and with the greatest comfort will excel anything ever known to the traveling public.

Almost 10,000 miles of railway are included in the marvelous system of the North Western Line. It reaches 2,000 active Western cities, towns and villages included in nine Western States, which are thus placed in immediate and vital touch with Chicago, the Great Central Market.

By traffic arrangements with its connecting lines practically every point west and northwest of Chicago is placed in direct touch with the city, by through passenger train service, and freight shipments are handled with precision and dispatch, consigned through to any one of 9,500 stations, located on 62,000 miles of railway, about one-eighth of the entire railway mileage of the whole world and one-fourth of the railway mileage of the United States.

The North Western Line is the pioneer line west and northwest of Chicago and the Only Double Track Railway between Chicago and the Missouri River. Its service includes

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

WAIST AND SKIRT SUPPORTER.—A. M. PRESTON, Braxton, Ga. The objects here are: to provide a supporter which is at once simple in construction, durable and certain in operation; to provide a device which will lie closely and snugly to the form, and to provide a device which is neat and presentable in appearance.

SELF SUPPORTING STOCKING.—G. GRAHAM, New York, N. Y. The invention relates more particularly to the means employed for supporting a stocking. The upper portion of the stocking is so formed that it in itself constitutes a garter, so that no separate supporting means need be employed. The invention covers any fabric foot covering, as for instance, socks, hose, half hose, etc.

Electrical Devices.

TROLLEY POLE CATCHER.—J. H. WALKER, Lexington, Ky. The purpose in this case is to provide a construction in connection with the pole and a lower connection, whereby the pole may be prevented from rising to a perpendicular position when the trolley wheel jumps the wire, and whereby the pole may be held in any intermediate position and may be permitted to freely move in contact with the wire in the operation.

Of Interest to Farmers.

JOURNAL FOR AGRICULTURAL IMPLEMENTS.—A. C. DITMAR, Davenport, Wash. An efficient journal is provided which can be attached to a plow beam or the like for the purpose of revolubly mounting a colter disk or other part, in which the disk can be set at any angle, which will fit any kind of plow, in which the spindle is in a dust-proof boxing and in which the wearing parts are supplied with lubricant.

ANIMAL COVER.—C. L. HASTINGS, Fond du Lac, Wis. The aim in this invention is to provide a durable cover which is particularly useful for cattle, by means of which the animal can be well covered when necessary, which thoroughly envelops the body, leaving the head, neck and legs free, and in which means are provided to prevent the displacement of the blanket from the rear of the body.

Machines and Mechanical Devices.

FILLING DEVICE.—J. PAPISH, 605 Freeman Street, Valparaiso, Ind. The aim is to provide in this invention a device by means of which powders, crystals or other granular material can be expeditiously and easily introduced into small-necked bottles and the like, which requires little effort to operate it, and which fills the receptacles without spilling any of the material which is being introduced into the receptacle.

Railways and Their Accessories.

DOOR.—C. B. WHITMAN, Watervliet, N. Y. This improvement in doors is especially designed to be used in connection with street railway cars, and has for its purpose to automatically register the number of passengers entering and which will permit of the exit without operating the registering mechanism. The movements of the motorman on the platform will not be more restricted than when the usual type of door is employed.

NOTE.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

INDEX OF INVENTIONS

For which Letters Patent of the United States were Issued for the Week Ending

November 30, 1909,

AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Accumulator, hydraulic, A. W. French	941,867

(Concluded from page 458.)

ous inland and Great Lake grain warehouses for transporting the grain horizontally from one part of the warehouse to the other Thus, when the wheat is shoveled out of the railway car into a spout below the open door, it will frequently happen that the transfer takes place at some distance from the particular one of the twenty elevator legs by which the grain is to be lifted to the top of the bin In this case it will be allowed to fall through onto a broad traveling belt of the kind shown in our illustration, upon which it will move swiftly until it reaches the spot at which it is to be delivered or "tripped." Here the belt will pass over a set of pulleys arranged above one another in such a way that the grain can be shot off the belt for such further handling as may be desired In this particular case it will be delivered to the boot of the elevator, carried up, and discharged to its own particular bin

Time saving is a great consideration in these huge warehouses, and one of the most interesting features is the system of swinging distributing spouts, intervening between the receiving and weighing bins at the head of the elevators and the huge honeycomb of storage bins below One of our views shows these spouts, hinged below the floor of the top story of the building and capable of being swung around and over the top of the particular bin to which the grain is to be delivered This arrangement is one of many ingenious arrangements by which the enormous mass and weight of grain can be received, weighed, placed in its own particular bin drawn away therefrom, lifted, transported horizontally and finally delivered to car or steamship in the least possible time, with unfailing accuracy, and at the minimum of cost

In the above description we have traced the grain from a farm in the Middle West to the hold of the steamship that would carry it to Europe. As regards the general system of receiving, selling, and distributing the grain, the same methods apply to the wheat which is consigned to the great flour mills, say, of Minneapolis, or to any of the centers in which it is prepared for the consumption of the masses.

◆◆◆

CHICAGO AND THE RAILROAD SYSTEM OF THE MIDDLE WEST

(Continued from page 447)

000 passenger station, that will be ready for occupation early in 1910 With one exception it will be the largest passenger terminal in the United States. Over thirteen acres of ground will be occupied by the station and station tracks The approaches cover thirty additional acres, fifteen acres being used for the north and the west approaches. The present station, with capacity for handling fifty thousand passengers per day, is now overtaxed, the new terminal will be capable of taking care of a quarter of a million people every twenty four hours.

The plans call for an elevated terminal, reached by two elevated approaches of four tracks each, and a train shed 800 feet long and 320 feet wide, that will contain sixteen tracks, each with a capacity of fifteen cars. The area of the basement is over two acres, the street floor of the station building covers one and three-quarters acres, the train shed, six acres. Altogether there will be practically ten acres of floor space devoted to public use. One of the most important features is the treatment of the train shed This structure will not have the usual long black expanse of sooty roof that offends the eye. The sixteen long tracks which will occupy the shed will be covered by what is known as the "Bush roof," in which the curve of the roof over each pair of tracks is broken by a concrete slot or duct, running the length of each track, and so placed that the locomotive funnels will discharge through it into the open air.

The electrification of Chicago steam railways inside of the city limits is at

Do You Deliver Goods?

"Built for Business"

We have not found a business in which the Rapid Commercial Power Wagon does not save money compared with the cost of delivering with horses.

Giving satisfactory service in 52 different lines of business. Saving money for their owners every day

Rapid Commercial Power Wagons

If you deliver goods in any shape or form, it is not a question of whether or not a Rapid Commercial Power Wagon will save you money—it is simply a question of which kind of a "Rapid" will best fit your business.

Write us the nature of your business. State how many wagons or trucks you now use and how many men are required on each, and our Traffic expert will send you an accurate analysis showing the comparative cost and the definite saving, between doing business the modern "Rapid" way and with the use of horses.

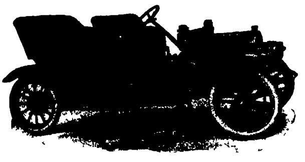
Rapid Motor Vehicle Co.

1112 Saginaw Street, PONTIAC, MICHIGAN, U. S. A.

By All Means Investigate

The Lambert Friction-Drive

Before You Buy Any Other Car



There are five models to select from, ranging from $900 to $1700.

Model 36, for five passengers, at $1275, is shown above.

It has a straight line body with a square front dash (very popular in the best 1910 Models).

A wheel base of 110 inches.

A tonneau that appears to have been made for a seven-passenger instead of a five-passenger car

Twenty-eight to thirty actual horse-power

Full elliptic springs in rear with semi-elliptic in front, giving to the Car an element of ease rarely found in any but the highest-priced cars.

A positive self-starting device that is added to the regular equipment at slight additional cost.

Full equipment.

For good roads or bad roads, for hills or sand, or big loads, the Lambert Friction-Drive operates with less annoyance, takes hold better and is far less liable to breakage than is the case with any other known form of transmission

Furthermore, the extreme simplicity of the friction-drive makes it by odds the most economical transmission for the motorist. Not only are there no costly gears to replace in case of "stripping," but should the friction-band become worn or injured, it can be replaced for about one-twentieth the cost of new gears.

Send for detailed information.

COPYRIGHTS &c.

INVENTORS are invited to communicate with **Munn & Co., 361 Broadway, New York,** or **625 F Street, Washington, D. C.**, in regard to securing valid patent protection for their **Inventions**. **Trade-Marks** and **Copyrights** registered. **Design Patents** and **Foreign Patents** secured

A **Free Opinion** as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question All communications are strictly confidential Our **Hand-Book** on Patents will be sent free on request.

Ours is the **Oldest** agency for securing patents it was established over sixty years ago.

MUNN & CO., 361 Broadway, New York
Branch Office 625 F St., Washington D C

Bearing for trough conveyers, etc., roller, H. Bentley	941 972
Bearing, roller, H. Hess	941 036
Bearings, means for introducing balls into ball, F. Geschke	941 652
Bed, folding, I. B. Jeffcott	941 879
Bed, folding, J. H. Edmonds	941 962
Bed, invalid, J. H. Comer	941 630
Bedstead mount buffing machine, J. F. Gall	941 706
Belt drive, A. G. Kolbe	941 786
Bench dog, F. A. Schade	941 810
Bill holder, J. H. J. Colleen	941 559
Binder, C. I. Wigginton	941 481
Binder, Wigginton & Hodges	941 482
Binder attachment, self, F. Leanington	941 045
Binding post, I. Steinberger	941 803
Blind stop, H. L. Beadle	941 553
Boat, C. Hoffman	941 123
Bobbin holder, S. W. Wardwell	941 785
Boilers, engine setting for horizontal, G. W. Morris	941 400
Book, manifolding copying, Whyte & Rau	942 023
Boot and shoe forms, holder for, T. F. McCann	941 725
Bottle caps, device for removing, Forsyth & Wallace	941 865
Bottle closure, Richards & Ahrfeldt	941 671
Bottle neck protector, A. Durand, Jr.	941 769
Bottle, nonrefillable, F. B. Barner	941 651
Bottle, nonrefillable, Jensen & Weitzel	941 984
Bottle receptacle, milk, A. G. Brodhead	941 873
Bottle stopper, D. Landau	941 788
Bottle, telltale, Midbo & Gulbrandsen	941 890
Bowling alley pin setting mechanism, L. A. Brigel	942 011
Box or container, J. F. Byrne	941 550
Brake apparatus, fluid pressure, M. Corrington	941 914
Buckle, I. H. Fishel	941 702
Building block, E. Chapman	941 617
Building block and wall, F. J. Schuster	941 646
Buoy, automatic locating, Marcou & St. Peter	941 777
Bushing and check valve, combined reducing, W. S. Jacobs	941 712
Bushing for pulleys, gears, and the like, H. G. Wolf	941 602
Cab signal circuit, F. J. Simmen	941 541
Cabinet, envelop, H. K. Smith	941 716
Cableway, T. S. Miller	942 038
Calculating machines, index plate for, J. Gruber	941 774
Calendar, E. C. Mahon	941 719
Camera, C. O. Perring	941 698
Camera, H. W. Comer	941 600
Can cap dropper, F. M. Cobb	941 357
Can closing device, J. H. Pelletier	941 563
Can heading machine, J. Brenzinger	941 735
Canceling machine, letter, I. Blessing et al	941 848
Candy pulling machine, H. S. Rowlington	941 610
Cane, wax like product obtained from sugar, A. Wynberg	941 401
Canopy frame having doors, W. S. Davidson	941 765
Canopy, ventilating, J. N. Mealy	941 095
Car, E. S. Buckman	941 845
Car heater, C. H. Anderson	941 601
Car controlling system, electric, A. B. Stitzer	941 791

Car fender, air actuated street, J. M. Clancy	941 407
Car fender, street, A. I. Mazzanovich	941 527
Car fender, street, G. J. Fleissner	941 084
Car for transporting ore or other material, W. C. Carr	941 405
Car hand, J. D. Kerr	941 420
Car heater, J. F. McElroy	942 040
Car, passenger railway, I. F. Laden	941 807
Car seats, wear strip and retainer for securing coverings to the frames of, F. H. Henry	941 878
Car wheel, motor, C. B. Winter	942 020
Cars or the like, system of precooling fruit, A. Faget	941 444
Carbureter, A. H. Warmsley	941 103
Carbureter, J. H. Cooper	941 408
Carbureter, C. G. Leonard	941 154
Carriage, folding baby, A. W. Laughbaugh	941 874
Carrier. See Stereopticon slide carrier	
Cash register, W. H. Muzzy	941 178
Cataloguing system, R. I. Chew	941 406
Cement block for wall structures, W. I. Davidson	941 624
Cement, process and apparatus for artificially aging or seasoning Portland, T. A. Edison	941 630
Chair, Brown & Goldberg	941 545
Chair, C. I. Greilick	941 910
Check controlled mechanism, F. C. Kaiser	941 716
Chocolate confections, machine for the manufacture of, A. H. Savy	941 537
Churn, D. Rees	941 048
Cigar, self lighting, D. G. Vale	941 098
Cigarettes, etc., machine for packeting, F. L. Bracy	941 100
Clamp, D. A. Ducharme	941 704
Clod crusher, C. O. Steiger	941 740
Clothes line hanger, G. T. Van Riper	941 898
Clothes rack, suspended, B. B. Bosworth	941 909
Clothes wringer, A. Lovett	942 001
Clutch, G. W. Brubaker, Jr.	941 973
Coal briquetting, O. E. Hite	941 454
Coating machines, holder for liquid, R. A. Beausejour	941 607
Coin collector, A. M. Farnsworth	941 500
Coke drag, S. Richter	941 383
Coke oven door, W. O. White	941 708
Collar, H. C. Miller	941 705
Comb, M. K. Purdy	941 [illegible]
Composing and casting machine, typographical, Pearce & Billington	941 594
Concentrator slime feeding device, J. B. Green	941 919
Concrete building construction, R. A. Woods	941 887
Concrete construction, metal tie for, E. Chapman	941 616
Concrete mixing machine, R. G. Leverich	941 906
Concrete pavements, laying, F. S. Lamson	941 896
Concrete pile, reinforcer, T. Stedman	942 018
Concrete wall mold, D. A. Marshall	942 004
Containing can, W. H. Hoyt	941 781
Conveyer, F. Ehrhart	941 884
Coop, poultry, J. A. Emert	941 567

(Continued on page 454)

(Continued from page 453.)

present a big problem to Chicago terminal lines and a popular subject with the people and the newspapers. Although an ordinance was passed by the City Council compelling Chicago railroads to provide other than steam power within two years it is frankly stated by the authors of the ordinance that they appreciate that the work cannot be done within this time but that they hope to see a start made toward electrification of Chicago terminals. At present the fight is centered on the Illinois Central Railway, the trains of which run along Chicago's otherwise beautiful lake front. The smoke and noise from the frequent suburban trains on the Illinois Central at the city's front door have accentuated the popular demand for a change in motive power.

It will be pertinent just here to give a few facts illustrating the magnitude of the business done by some Western roads and the punctuality with which it is carried on. Subsequently to an announcement by one of the leading Eastern roads that one of its crack trains between New York and Chicago had been on time during 123 consecutive days, the Burlington route drew attention to the fact that the Denver Limited ran the distance of 1,026 miles into Denver from Chicago on time for 136 consecutive days and that it was on time 531 days out of 546 days from January 1st, 1908, to June 30th, 1909. That there has been a gratifying improvement in the safety of railway travel is shown by the fact that this company carried over 19,000,000 passengers during the past year and that not a single one of these was killed. A similar creditable record is reported by the St. Paul, the Northwestern, the Santa Fé, the Rock Island and the Alton roads. The Burlington system alone employs 42,100 officers and men, owns 1,703 locomotives and 52,403 freight cars, carried during the past year 32,379,520 tons of freight and its receipts amounted to $78,500,000, an increase of about 100 per cent in ten years. Another instance of the volume of business in and out of Chicago by rail is afforded by the Chicago & Alton Railway, which on a mileage of 998.8 miles moved 9,668,927 tons of freight, carried 3,828,056 passengers and received and forwarded at Chicago 3,749,920 tons of freight.

Modern Improvements in Track and Rolling Stock.—The present necessarily brief survey of railroad conditions in Chicago and the Middle West would be incomplete without some reference to the really remarkable improvements which have been made during the past twenty-five years both in the roadbed and in the rolling stock. The pioneer roads, built when capital was scarce and extended into countries in which they had to literally create the traffic from which returns upon the investment could be made, were necessarily, if we may be excused the expression, "cut according to the cloth." "Cheap first cost" was the controlling motive of their construction, and the locating engineer was told to lay out his line with as little disturbance of the surface of the ground as possible. Hence he ran his survey around the hills or over them by steep grades instead of through them by cut or tunnel. His line ran down into the valleys or crossed them by cheap timber trestles. Wood was used in place of costly steel for the bridges over streams and rivers. The ties were frequently laid directly upon the surface of the ground with practically no ballast beneath them; the steel rail was of the lightest weight which could carry the engines and cars. Twenty-five years ago fifty tons was the average weight of the engine, and twenty tons was the maximum load for a car. The grades over the mountain were frequently two per cent, and sometimes ran up to three per cent or over, thereby greatly limiting the load which any one engine could haul over a given stretch of land.

With the settlement of the country and the development of the passenger and freight traffic the various railroad com

(Continued on page 455.)

The NEW INVINCIBLE SCHACHT

Three Cars In One

NOTE THESE FOUR FEATURES:

FIRST—**Its price, only $875.** No other car on the market selling at anywhere near this price has the style, the **real automobile** appearance that this car presents. (Most cars at this price belong in the "near-car" class.)

SECOND—**As a Runabout,** it is an ideal car for the business or professional man, or the farmer who wants a light, handy car for business purposes or cross-country trips.

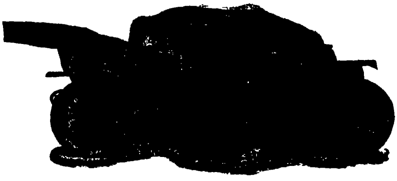
THIRD—**With surrey-seat attachment** it supplies a roomy four-passenger family car **with no extra cost.**

FOURTH—**With parcel delivery attachment** it becomes the handiest **general utility** car on the market, and will be a big favorite with merchants and farmers who have constant use for a car of this type.

Let us send you additional information about this excellent, **general utility** car

SCHACHT MANUFACTURING COMPANY

2700 SPRING GROVE AVENUE **CINCINNATI, OHIO**



You will Buy this Haynes Model 19—$2000 If you want Known Quality Without Fancy Price

It is an innovation in automobiles.

No other manufacturer has ever attempted to give so much of real **tone** in a car selling at this price, and the payment of a **thousand dollars** more cannot buy a nicer-running engine or an easier-riding car.

It is the **only** car **of established reputation** selling at a moderate price.

A ride in it will be a revelation to you—especially if you have owned other cars. Its flexibility, the power of the engine, the resiliency of the springs, the upholstering—all are of the character that you would expect **only** in cars carrying a much fancier price.

Some idea of the attitude of both automobile dealers and the public respecting a **Haynes at $2000** can be gathered from the fact that dealers bought up our entire output of 1910 cars **within thirty days** after our first public announcement, and inquiries from over six thousand interested parties have been received. If you contemplate buying a car **of real worth,** we recommend that you communicate either with us or local agents **without delay.**

(*Continued from page 454.*)

panies began to find themselves in a position to bring their roadbed and rolling stock up to a higher standard, suitable to the rapidly increasing movement of freight and passengers, and during the past fifteen years hundreds of millions of dollars have been expended in this work. Much of the track has been relocated, curves have been eased or eliminated altogether, grades have been cut down, timber trestles have been replaced by solid earth or rock embankments, wooden bridges have given place to massive structures of steel, heavy grades over the mountain summits have been eliminated by the simple but enormously costly process of tunneling right through the solid mountain itself, millions of tons of rock ballast have been distributed and tamped beneath the ties, and the light rails of 56 to 60 pounds weight to the yard have given place to rails weighing from 75 to 90 pounds.

Furthermore, many of the important western railroads are double-tracking their lines. The Santa Fé is building double track for its main line between Chicago and Kansas City, and beyond as far as Newton, Kansas. Between Chicago and Newton 644 miles of second track are now in operation, having been recently built at a cost of $22,500,000. Between Chicago and St. Paul and Minneapolis, the St. Paul road has been pushing to completion the double-tracking of its main line; and between Chicago and Omaha the Northwestern Railway has already completed its double track, and the Burlington road will complete the same work at an early date.

The transcontinental roads which have been built during the past few years will, of course, be spared these costly expenses for betterments. In a recent issue of the SCIENTIFIC AMERICAN SUPPLEMENT we gave a complete description of the Pacific Coast extension of the Chicago, Milwaukee & St. Paul. On the afternoon of March 29th of this year the last rail of this extension was laid. It is now known as the Chicago, Milwaukee & Puget Sound Railway. The first shovelful of earth on this enterprise was turned in April, 1906, so that the whole of this $100,000,000 enterprise was completed in three years' time.

The improvement in railway track has been fully matched by the development of the rolling stock. Freight cars have increased in capacity from 20 tons to 50 tons, passenger engines have increased in weight from 50 tons to 135 tons, and freight engines from 60 to 70 tons have gone up to a weight of 213 tons—the above being the weights merely of the engines alone. The largest passenger engines are the magnificent six-coupled ten-wheel engines used on the New York Central and allied roads and built by the American Locomotive Company. They have cylinders 22 inches in diameter by 28 inches stroke, coupled to three pairs of 79-inch driving wheels. The boiler, 6 feet in diameter, has 4,195 square feet of heating surface. The engine alone weighs 130.7 tons and the maximum tractive power is 16.7 tons. These engines can haul as many as fourteen Pullman cars, or say about 800 tons of train on the level at 55 to 60 miles an hour.

Even more striking has been the growth in weight and power of freight locomotives, especially since the introduction of the articulated type. The largest and most powerful of these is a mammoth affair built by the Baldwin Locomotive Works for the Mountain Division of the Southern Pacific Railway. It is a compound with two high-pressure cylinders 26 inches diameter by 30 inches and two low pressures 40 inches in diameter by 30 inches stroke. The boiler has 6,393 square feet of heating surface. The engine alone weighs 213 tons and the engine and tender together weigh just under 300 tons. This engine is capable of taking a 2,000-ton train over the heavy grades of the Mountain Division of the

American Homes and Gardens

FOR DECEMBER, 1909

Here are some of the articles it contains

MAKING SOIL

A helpful paper by E. P. Powell in which he tells some of the simple methods employed by farmers in adding to the value of their soils. A practical note of unusual interest

COLONIAL FIREPLACES AND FIRE-IRONS

Mary H. Northend contributes an entertaining and suggestive essay on Colonial fireplaces and fire-irons, which is richly embellished with many beautiful photographs taken expressly for this paper. Miss Northend briefly traces the early history of the fireplace in America and has prepared a paper of great interest.

ART AND HOUSEHOLD DECORATION

An editorial comment on the true relationship between the home and its artistic decoration. Some useful facts put in a strong and forceful way

DEPARTMENTS

Problems in Home Furnishing. Conducted by Alice M. Kellogg.
Garden Notes. Conducted by Charles Downing Lay
New Books.
Grafting for Boys. A practical article telling how boys may engage in this interesting work and the successes some of them have attained in it.

The First Prize in the Garden Competition

The garden adjudged the first prize in the recent garden competition conducted by this magazine forms the subject of the opening article in the December number. This is a charming and delightful place abounding in picturesque developments very ably utilized and beautifully developed. The illustrations, which include several full-page plates, are very numerous and of the deepest interest

A New Artists' Home

The beautiful, yet modest, home of Mr. and Mrs. Robert V. V. Sewell at Oyster Bay constitutes a notable contribution to Barr Ferree's series of papers on the homes of American artists. This house easily stands among the most notable private dwellings in America. Mr. Sewell, a painter of national renown, has lavished of his genius and his work in a remarkable embellishment of hand wood-carving, all executed by himself, which gives an intensely personal character to the house and is its distinguishing characteristic. This house has not been published heretofore.

Hammering and Piercing Metal

Mrs. Mabel T. Priestman contributes a valuable and practical paper on the craft of hammering and piercing metal. This is an interesting and fascinating form of craftwork that any one, with Mrs. Priestman as a guide, can readily follow. The illustrations show clearly how this work is done, and offer many interesting practical designs.

Bungalow Furnishing

Kate Greenleaf Locke, whose article on four California bungalows is a distinguishing feature of the present number, opens up a new theme in bungalow literature with an eminently readable and suggestive paper on interior bungalow detail and furnishings. Miss Locke offers a number of helpful and valuable suggestions on the treatment and equipment of bungalow interiors, and illustrates her paper with numerous and beautiful photographs taken expressly for the article.

A Concrete Fence

Ralph C. Davison's series of papers on concrete garden ornaments and how to make them is brought to a close in an interesting paper on the methods of building a concrete fence. The text is very precise and definite and is especially intended to enable any one to build his own fence from the directions given. The illustrations are especially numerous, and include both diagrams and half-tones. It is a fine article of great practical value

Some New Western Homes

Francis Durando Nichols, who has been gathering material for the magazine in the West, offers the first fruits of his work in a valuable paper on some new Western homes. The illustrations are chiefly of Chicago houses and open up an entire new school of architecture to our readers. Mr. Nichols will have more to say on this subject in future numbers, but the first article should not be missed.

Price 25 cents on all newstands

DESIGNERS AND BUILDERS OF

Grain Elevators

Chicago, Ill.——Montreal, Que.

(Concluded from page 455)

Southern Pacific and on the level it would be capable of hauling a train weighing 10 000 tons and carrying about 7 000 tons of freight at a speed of ten miles an hour

◆

CHICAGO'S SIXTY MILES OF FREIGHT SUBWAY

(Continued from page 448)

not even excepting New York The many trunk railroads which center in Chicago have done their best to shorten the haul to and from the freight terminals and the various business houses for if one looks at a map of Chicago it will be seen that these terminals are located in the very heart of the city and that they have reached a point beyond which because of the high value of land they cannot possibly go

The credit for the solution of the problem of freight distribution is due to Albert G Wheeler, who several years ago applied to the City Council for a franchise on behalf of the Illinois Tunnel and Telephone Company for the construction of a system of tunnels which should be used for the transmission of sounds, signals, and intelligence by means of electricity or otherwise The franchise was granted and work was commenced in a very unostentatious manner the necessary capital being found by private parties The lines as now completed extend from Armour Avenue and Archer Avenue on the south to Chicago Avenue and Kingsbury Street on the north to Green Street on the west The greater part of the sixty miles of tunnel is six feet in width and seven and a half feet in height but there are also trunk tunnels which are twelve feet in height and vary in width from ten to fourteen feet It was stipulated that the floor of the tunnel should be about forty feet below the street level and as it is generally seven and a half feet high it follows that the tunnel roof is about thirty three feet below street level By constructing the system at this depth all interference with the water and gas pipes and sewers of the city was avoided, and sufficient room was left for the construction of a complete passenger subway system between the street surface and the tunnel whenever the city should be prepared to take up such a work

It was stipulated in the franchise that the tunnel must be built below the center line of the streets and this has been done In prosecuting the work shafts were sunk as a rule in the basements of various buildings which were rented for the purpose of the tunnel company and these basements were used for mixing the concrete and for installing the air compressing plants which supplied the necessary air at ten pounds pressure for the pneumatic system under which the whole work was prosecuted From the shafts above mentioned the workmen drifted out to the center of the street where the work of excavation was carried on in opposite directions In the earlier years of construction the material was hoisted to street level loaded into contractors carts and hauled to the dumping ground on the lake front this work being done entirely in the night time to avoid any interference with the already crowded traffic of the day time In later years the dump cars have been run to the surface by means of an incline and hauled by electric locomotive to the lake front,

THE AUTOMOBILE NUMBER of the SCIENTIFIC AMERICAN

On January 15, 1910, the Scientific American will issue its

ANNUAL AUTOMOBILE NUMBER

this year bigger and even better than it ever was.

It has been our purpose in publishing this annual review to give the automobile owner and the prospective purchaser truly helpful information, and to that end the number will contain the following articles:

1 *The Automobile and the Farmer*
An article that shows what the automobile can do and what it is doing for the farmer, in carrying produce to market.

2 *How to Overhaul Your Car*
An article that instructs the reader specifically how he should take down, examine and put a machine in first-class condition for a season's work.

3 *The Automobile Fire Engine.*
All the latest automobile pumping engines, chemical cars, hook and ladder trucks, and hose carts are described

4 *The Automobile and the Road.*
The automobile has presented to the road engineer new problems for solution. He must render his roads impervious to water and practically proof against the destructive effect of tires. The United States Government through the Office of Public Road Inquiry is now studying this subject. The article written by Mr Page, Director of the Office of Public Roads, describes what has been done.

5 *Anti "Joy Ride" Devices.*
This article is a complete description of devices which have been invented for the purpose of preventing chauffeurs from taking out their owners' machines.

6 *The Modern Electric Automobile*
A safe, sane, impartial account of the improvements which have been made in the electric pleasure vehicle and which are destined to stimulate the demand for an inexpensive, clean, smooth-running automobile.

7 *Making Your Own Repairs.*
In this article the handy man is told how he can circumvent the garage keeper by making his own repairs. Simple mechanical drawings elucidate the text.

8 *The Cars of 1910*
Illustrations of the chief cars of 1910, with their leading dimensions and characteristics A bird's eye view of the entire automobile field for the man about to purchase a car of any price.

9 *Automobile Identification Chart*
Sometimes you have wondered what make of car was that which skimmed past your admiring eyes. The 1910 Automobile Number will enable you to identify any car by its radiator and engine bonnet. About thirty-five automobiles are thus illustrated for identification in a sketchy, artistic way

10 *The Inexpensive Car*
Any man with a good salary can now afford to own some kind of an automobile. How the machines are constructed and what may be expected of them is lucidly set forth.

11 *The Wonderful Rise of the Automobile Industry*
How the motor-car industry grew from nothing to an industry capitalized at many millions, how the scene of its manufacturing activity has shifted from the East to the Middle West, and how the American car is gradually displacing the imported machine.

12 *Automobile Novelties.*
In this article inventions are described which increase the reliability of the automobile.

(Continued on page 457)

(Continued from page 456.)

where already an addition has been made to the area of the city's park of about twenty acres. As the average fill is forty feet in depth, it can be understood that, had this enlargement been made by the city itself, it would have cost about $690,600.

The system is operated entirely by electricity, and the equipment consists at present of 175 motors of the Jeffrey and the General Electric types and 3,509 cars. There is a telephone installed on every block, and the movements of the trains are directed entirely by this means.

Although the wording of the franchise would indicate that the tunnels were to be constructed primarily for the installation of telephone and telegraph lines, it will be understood that the greatest revenue-earning power will be derived from the transportation of freight. It is estimated that about one hundred thousand tons of freight are hauled through the streets of Chicago each day, and if the tunnel company should haul only one-third of this, the total for the year would amount to over ten million tons. Hitherto no great effort has been made to push this branch of the business, but now that the system is about completed, it is expected that full connections will be made with the various business houses, and great increase in traffic will follow. Connection between the various warehouses and the tunnels is made by sinking a shaft and equipping it with electric elevators, which run from the track level below to the particular floors of the warehouse upon which the freight is to be delivered. In the case of a big warehouse, such as Marshall Field & Company, the loaded cars are hoisted to the desired floor, unloaded, loaded with the outgoing freight, returned to the tunnel, and drawn to the particular railroad freight station desired. It will not, of course, be possible to have direct connection between warehouse and tunnel in every case, and hence central depots will be provided at various suitable locations throughout the city, so placed that the average haul by team will not amount to more than one or two blocks. One immediate advantage of the system is that the wholesale houses are now able to carry on business throughout the twenty-four hours of the day. Under present conditions, after the teams have gone home for the night, the goods that are ready for shipment have to wait until the following day, and at busy seasons of the year it is not unusual for a delay of several days to occur. By using the tunnel system, the merchant can make immediate shipments of his freight, whether it consists of one truckload or fifty.

The tunnels will serve many useful purposes outside of that of transportation of merchandise. One of these, and a very important one, is that of the hauling away of material from the excavations for buildings within the city. Hitherto, this has been done by teams upon the surface, but the present method is to run a steel chute from the excavation down to the tunnel on an angle of about forty-five degrees. The workmen wheel the material to the mouth of the chute, and dump it, and it is received and drawn away by cars, which are successively moved below the mouth of the chute in the tunnel. When a train has been made up, an electric locomotive hauls it to the dump on the lake front. By this method as much as 2,100 cubic yards of material has been removed from the basement of a single building in one day. The best that has ever been accomplished by teams in the same time is 420 cubic yards. Another important service rendered is that of bringing coal to the boiler plants of the various houses and the hauling away of ashes and other refuse.

In no direction has the tunnel proved more successful than that of the transportation of mail. A twelve by thirteen-foot subway has been constructed below the United States Post Office building, en-

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 10 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres. The Nat'l Co-op. Real Estate Co., Suite 378, Marden Bldg., Washington, D. C.

Inquiry No. 8918.—For manufacturers of "Wydt's Electro Catalytic Sparking Plug."

WANTED. Machine to manufacture a special Safety Pin (all wire). I prefer to get it made by some company in quantity lots, or on royalty. For particulars, address J. H. Reed, Lancaster, Wis.

Inquiry No. 8927. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

WILL PURCHASE COMPANIES now in operation or furnish capital for promoting franchises for gas companies, trolley, water, electric light, or natural gas, patents or other good enterprises. For information, address C. L. Gallagher, Prudential Bldg., Newark, N. J.

Inquiry No. 8996.—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

EDUCATIONAL.

CIVIL SERVICE EMPLOYEES are paid well for easy work; examinations of all kinds soon; expert advice, sample questions and Booklet 25 describing positions and telling easiest and quickest way to secure them free. Washington Civil Service School, Washington, D. C.

Inquiry No. 8990. For information regarding shoes not made of leather but similar to the same and are as durable.

PATENTS FOR SALE

FOR SALE. Patent No. 920,487. An improved lathe rest for holding cylinders while being bored in an engine lathe. For further particulars address A. B. Whiting, Weston, W. Va.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium tipped gold nib making for fountain pens.

FOR OUTRIGHT SALE.—U. S. Patent No. 924,293. Canadian Patent No. 120,768 agricultural implement, that will revolutionize the present methods. Most important since the Binder. Effectively whips the soil from the roots of weeds, etc., and pulverizes the soil, hence better crops, no more weeds, and less labor. Actuated by motor power and applicable from smallest gardens to largest farms. Address Nathan Tripp, Sub Station No. 8, Grand Rapids, Mich.

Inquiry No. 9016. Wanted machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

FOR SALE

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads, 8 to 40 in. Price only $48.50. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9023. Wanted to buy silk machines from re-reeling, twisting, doubling to the final process of making it into clothes.

PARTNERS WANTED

YOUNG energetic electrician, German, wants a partner with sufficient capital to cover expenses of patents and models in mechanical lines for my original inventions. Write T. Roman, 425 E. 169th St., New York City.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

AN INTEREST in Patent No. 925,086 will be given a responsible firm who will manufacture and place on the market a novelty, and an improvement on a staple article for which there is a large sale. Small amount of capital would probably be needed. Partner, Box 773, N. Y.

Inquiry No. 9028.—Wanted, to buy a washing machine that is run by a coil spring motor.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9034.—For manufacturers of machinery that could reduce stumps to kindling wood.

Inquiry No. 9036. Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

Inquiry No. 9042.—Wanted the address of Farney Safety Razor Co.

Inquiry No. 9044.—Wanted to buy outfits necessary for agate polishing.

Inquiry No. 9046. Wanted, machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

Inquiry No. 9047.—Wanted, the address of parties who install plants for making oxygen ozone gas.

Inquiry No. 9048. Wanted, address of manufacturers of metal table slides for extension tables.

Inquiry No. 9049. Wanted to buy rotary brushes suitable for a shoe shining machine.

Inquiry No. 9050. Wanted to buy equipment for manufacturing starch and denatured alcohol from potatoes, also manufacturers of equipments for vegetable canneries.

Inquiry No. 9051.—Wanted to buy machinery for extraction of cotton seed oil on a small scale.

Inquiry No. 9052.—Wanted to buy machinery, etc., for a beer plant, that manufactures beer by means of glucose.

Inquiry No. 9053.—Wanted, address of firms who install plants to manufacture nitrogen.

Inquiry No. 9054.—Wanted, address of manufacturers of articles made from mica.

(Concluded from page 457.)

tending from Jackson Boulevard to Adams Street. The mail is thrown down chutes from the mailing platform to the platform of the subway, where the pouches are placed in the cars of the company and sent on to their destination. In the receiving of the mail at the Post Office, the pouches are unloaded from the cars onto a thirty-inch belt, which carries them up an incline to a point just below the driveway, where a cross-belt receives them and delivers them onto the mailing platform. For this work the tunnel company employs sixty-six electric motors and one hundred and fifteen cars. During the year 1907, the electric mail trains made 337 060 trips and carried 10,059 567 bags, pouches, and packages of mail, with a record of 99 51 per cent perfect as regards the time of delivery at the various tunnel stations. On the day before Christmas of that year the tunnels handled over 50,000 bags, pouches, and packages, which were transported in 1,391 cars and in 1,229 trips.

It can be readily understood that a complicated transportation system such as this, involving an enormous number of cross-overs and switches, demanded for its safe and uninterrupted operation a very complete system of signaling. The method adopted is what is known as the Stolken train-signaling system, the invention of Mr. J. J. Stolt and Mr. W. J. C. Kenyon, the vice-president of the tunnel company. Limitations of space prevent any detailed description, but in brief the system may be described as one which does not employ track circuits, but which embodies two distinctive adaptations, first, the absolute protection of an intersection of two tracks and secondly, the maintenance of a signal or alarm for a definite time after a circuit closer has been actuated. The method is automatic. For the protection of an intersection of tracks on each of which there is traffic in only one direction, red signal lamps are employed which are lighted by an approaching train. These lights are so placed that warning is given to a train on the other track and to any train which may be approaching from the rear. After the train has set the warning signals, it crosses the intersection and as it passes on restores all the signals to the "clear" or no signal condition. In addition to the red lamps, a green lamp is provided on each track, which indicates to the motorman of an approaching train that his signals are working properly, and so gives him permission to go ahead.

Instructive Scientific Papers
ON TIMELY TOPICS
Price 10 Cents each by mail

ARTIFICIAL STONE. By L. P. Ford. A paper of immense practical value to the architect and builder. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

THE SHRINKAGE AND WARPING OF TIMBER. By Harold Busbridge. An excellent presentation of modern views; fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER. By N. Monroe Hopkins. Fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

DIRECT-VISION SPECTROSCOPES. By T. H. Blakesley, M.A. An admirably written, instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No. 1493.

HOME MADE DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 161 and 600 contain excellent articles with full drawings.

PLATING DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them.

DYNAMO AND MOTOR COMBINED. Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS 844 and 865. The machines can be run either as dynamos or motors.

ELECTRICAL MOTORS. Their Construction at Home. SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641.

PENNSYLVANIA R.R.
Reminder Bulletin

There are two trains that the world is watching. They are making records, and records on land and sea and in the air are watched these days. The
PENNSYLVANIA SPECIAL
is saving time and money to the business man by permitting him to snap down his desk at 4 o'clock and meet his associates in Chicago the next morning as they open theirs. In the mean time he may continue his business with a free stenographer at his elbow, or loaf with the conveniences of the club at hand.

The "Special" leaves Uptown New York at 3 55 P M, Downtown by Ferry at 4 00 P M, Downtown by Hudson & Manhattan Tube at 4 05 P M, and arrives in Chicago next morning at 8 55. It kills time because it runs in the night.
"The 24-Hour St. Louis"
is giving the business man an entire afternoon for recreation at the club, or elsewhere. He may leave Uptown New York at 6 25 P M, Downtown at 6 30 (by Ferry), Downtown at 6.35 by Hudson & Manhattan Tube and reach St. Louis at 5 25 the next afternoon. He may enjoy a good night on an easy-running train and continue his work the next day with a stenographer at his beck and call, or he may do anything he can do at his club except play billiards.

He gets a whole day in New York.

These trains are not only time-savers, but nerve-resters.

They exhilarate and refresh. They may be banked on for time.

"AERONAUTICS"
How to Build a Flying Machine. Read the descriptions of successful machines. The news of the world told concisely, comprehensively and interestingly. Practical articles and construction data. The only Aero Journal in America—the largest and best aero magazine in the world. Third year. Send 10 cents for sample copy.
"AERONAUTICS," 1777 Broadway, New York

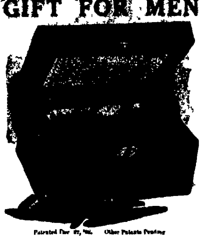
THE WELCOME GIFT FOR MEN



Patented Dec 27, '04. Other Patents Pending

50 Sargent Perfectos . . (Regular Price $3.50) } **$3.50 for Both**
Sargent Patent Cigar Chest (Regular Price $3.50)

You take no risk by buying with our "Money Back" Guarantee

Every smoker will be glad to get a box of Sargent Cigars. Every man who smokes should have a Sargent Cigar Chest to keep his cigars in prime condition. The two together at the price of one is an offer hard to resist. It is the ideal Christmas gift for men.

Sargent Cigar Chest FREE

The Sargent Patent Cigar Chest (shown above) is a perfect little cigar store in itself. It is made of oak, mission finish, glass-lined and sanitary. No pads or sponges to bother with, the moisture being supplied by a new process. With a Sargent Cigar Chest you never lose money on dried-out cigars. The chest will be sent you with your first order and is your property even if you never buy another cigar of us.

OUR "MONEY BACK" GUARANTEE

If cigars and chests are not up to your expectations, send them back at our expense and we will refund your money without question. Send us $3 50 and we will ship you 50 Sargent Perfectos and the Cigar Chest. If you order 100 cigars, price $7 00, *we will prepay express charges on cigars and chest anywhere in the United States.* Subsequent orders for cigars filled at $7 00 for 100; $4 10 for 50.

For $2.00 extra we will send a mahogany chest instead of oak; or for $3 00 extra, one of Circassian Walnut.

Do You Gamble?

Some people spend their money and energy housing a splendid crop of grain, cotton or tobacco and then gamble with Providence on its safety until sold. Do you?

Other people put the savings of years into a home and then rely on their luck to avoid the thousand-and-one chances of fire. Do you?

Still other people invest their entire assets in a store or factory and then wholly or in part insure themselves thinking that they can carry the risk as well as the insurance company. Do you?

The average man has most of his property in one place. To carry his own insurance is to depend upon chance i. e. to gamble with ruin as the penalty for losing. The business of the insurance company is founded on the law of averages. It can be safely conducted but only when its stability is based on the experience of tens of thousands of risks widely distributed over a continental area.

The Hartford Fire Insurance Company offers unsurpassed indemnity. Its business is distributed among more than fifteen thousand cities, towns and villages throughout the United States and Canada. During 99 years it has paid every just claim more than $125,000,000 in all. Its policies are safeguarded by ample resources and an honorable record.

The Hartford insures all classes of property. It also serves property owners by telling them how to guard against the dangers of fire. It has published a book on the subject with separate chapters for householders, merchants and manufacturers, that will be sent free to those who apply for it.

A REVERSION TO TYPE

The old American eight wheel passenger locomotive, with its flexible wheel base and comparatively high center of gravity, was admirably adapted to the tracks on which it ran. When, a few years ago electric traction was applied to our steam railroads, the designers of the electric motors made the mistake of ignoring altogether the steam locomotive, and basing their designs upon electric street car practice. Consequently, the first electric locomotives for this work were in respect of their driving mechanism, nothing more nor less than exaggerated trolley cars, with the characteristic rigid wheel base and a low center of gravity.

When the plans of the electric locomotives for the New York Central and New Haven railroads were made public, the SCIENTIFIC AMERICAN criticised these features, and predicted that they would prove very destructive to the track particularly in their tendency to throw it out of alignment. The wreck at Woodlawn, followed later by another at Greenwich established the truth of these criticisms and both locomotives have subsequently been modified, with a view to eliminating as far as possible the defects referred to.

In designing the powerful electric locomotives for the Pennsylvania tunnels which are illustrated elsewhere in the present issue the defects of rigid wheel base and low center of gravity were avoided by removing the motor from the axle and placing it above the frames and by reverting to the wheel plan of the American eight wheel type, in which there are four coupled drivers and a leading four wheel truck. It will be seen that if a pair of cylinders were placed above the truck, and the jack-shaft cranks and the coupling rods to the motor were replaced by a crosshead and piston, we would have the familiar steam locomotive arrangement.

It will thus be seen that the locomotives are a compromise between the existing steam and electric locomotives, with the best features of each included. They will combine the even turning effort and absence of unbalanced weights of the electric, with the high center of gravity and flexible wheel base of the steam locomotive. Whether this is destined to be the enduring type, is a matter for the future to determine.

NAVY DEPARTMENT REORGANIZATION

Since the new plan for the reorganization of the administration of the navy is described by its sponsors as "tentative" they evidently expect that experience will suggest some modifications. This being the case we have no wish to indulge in what might seem to be captious criticism for we believe that the Secretary has given his indorsement to the present plan only after a very serious consideration of its utility. Furthermore, we have personal reasons for believing that many of the naval officials who have taken an active part in the recent criticisms and discussions are weary of the protracted controversy, and are anxious to welcome any plan which gives promise of harmonious and economical administration.

Surely if special boards have done anything to solve the problem we ought by this time to have reached a clear road. The Sperry board, the Leutze board, and lastly the Swift board, were appointed, made their investigations, and duly reported to the Secretary. The present scheme may, therefore, be taken to represent the combined wisdom of the many selected experts who have passed upon the subject.

On one point, however, we do doubt most strongly the wisdom of Secretary Meyer's proposed scheme. We refer to the proposal to take the administration of the navy yards out of the hands of the naval constructors and put the seagoing officers in control. Look at the matter whatever way we will, this move seems about as unreasonable as to take the captains and executive officers of the transatlantic liners from their ships, and place them in full control of the yards in which their ships were built. Our seagoing officers have not the experience or the special technical and mechanical knowledge to qualify them for the position of "works managers." An officer may have a perfect genius for naval strategy and tactics, he may have the most intimate knowledge of seamanship in its broadest sense, of navigation, and, in short, of everything that has to do with the management of a warship when she is in commission, and yet be a very poor mechanic, and have only a very hazy idea of shop and yard management.

If it be necessary—and we believe it is—for the present scheme of reorganization to receive the sanction of Congress, we trust that body will make a very exhaustive investigation of this phase of the question. The Newberry scheme, which has now been for about a year in successful operation established the naval constructors in practical charge of the administration of the yards, subject to a commandant, it created a single payroll, and placed the care of buildings and grounds, and of all the work coming under the head of civil engineering, under a single manager. The number of separate shops was greatly reduced and the officers in charge of the various shops were practically inspectors of the work done for their several bureaus. The work of the yards was greatly simplified, expenses were reduced, and there was a greater all round efficiency. We trust that Congress will modify the proposals of the present scheme as far as they affect the navy yards, and permit them to be run under the present admirable plan. If this modification be made, we believe that Secretary Meyer's reforms will prove to be of lasting benefit to the navy.

THE VALUE OF EXHAUST STEAM.

Apart from its own inherent excellence as a prime mover the steam turbine has been teaching us many valuable lessons about the steam engine, or, to speak more correctly, has been bringing into prominence many facts regarding the steam engine which were known but whose great importance was being overlooked or neglected. We have all of us known in a general way for instance that a high pressure engine exhausting directly into the atmosphere was extravagant, but it remained for the low-pressure steam turbine to teach us how much power was being lost, and what a large proportion of that power could be recovered by expanding the steam down in a suitable auxiliary chamber. It has already been established that when an exhaust steam turbine is installed as an auxiliary to a non-condensing engine, it can develop from the exhaust steam even more useful work than the engine does from the live steam. Proportionate economies also are realized where an exhaust steam turbine is interposed between the low pressure cylinder of a compound or triple-expansion engine and the condenser. A notable instance of this is found in the 59th Street power station of the New York Subway, which was originally equipped with the well known Allis-Chalmers cross-compound engine.

The maximum economical rated power of these engines, as contracted for, was 6,000 kilowatts, with an overload capacity of about 8000 kilowatts. At their normal rating, the engines showed a water rate of about 18 pounds of steam per kilowatt hour, and at maximum overload the consumption ran up to about 22 pounds. By interposing a low-pressure turbine between the low-pressure cylinder and the condenser it has become possible not only to run the engines with an economical water rate at their full overload, but the total kilowatt output is about doubled, the combined unit developing about 16,000 kilowatts on a water rate of 14 pounds per kilowatt hour. The steam enters the high pressure cylinders at a gage pressure of from 190 to 195 pounds, the low pressure at from 45 to 48 pounds, the turbine at about one pound, and the condenser is maintained at about 28.8 inches of vacuum. In the expansion from 195 pounds gage to atmospheric pressure 8000 horsepower is developed, and by the interposition of the steam turbine another 8000 horse-power is recovered between the atmospheric pressure and 28.8 inches of vacuum. This is a wonderful advance in steam-engine practice, but that we are still far removed from theoretical perfection is proved by the fact that, even with this successful combination, 60 per cent of the heat units is being carried away by the condenser water into the North River.

A STEAM-TURBINE ELECTRIC LOCOMOTIVE.

Considerable interest has been aroused in British railroad circles by the announcement that the foremost locomotive construction company have perfected a new type of railroad engine, particulars of which were recently given to a Scottish university engineering society by the president of the company in question. It is described as a "steam-turbine electric locomotive," and as a turbo-electric combination. The first engine of this type, which is approaching completion in the company's shops, possesses many new and ingenious features.

In general design the engine will not differ very materially from the ordinary locomotive now in use. Steam is raised in a boiler of the usual locomotive type, fitted with a superheater, the supplies of water being drawn from tanks disposed on either side of the boiler, and the coal is carried in side bunkers. The steam is led from the boiler to a high-speed impulse turbine running at 3000 revolutions per minute, to which is directly coupled a continuous-current, variable-voltage dynamo. With this generator electrical energy ranging from 200 to 600 volts is supplied to four series-wound traction motors, the armatures of which are built on the four main or driving axles of the locomotive.

The exhaust steam from the turbine is passed into an ejector condenser, and is finally, with the circulating condensing water, discharged into the hot well. Owing to the steam turbine requiring no internal lubrication, the water of condensation is free from oil, and can consequently be discharged from the hot well direct into the boiler by means of a feed pump. In this manner the water can be used over and over again, and the water carried in the supply tanks actually serves as circulating water in the condensing operations. Circulation is effected in a closed cycle by means of small centrifugal pumps, driven by auxiliary steam turbines, placed alongside the main turbine and dynamo. The water thus flows from the tanks through the first pump, by means of which it is forced through the condenser, where it serves to condense the exhaust steam from the turbine, then to the hot well, from which it is pumped to a cooler at the front of the engine, where it comes into contact with a blast of cold air caused by the movement of the locomotive and a fan which serves to cool it, and then it returns to the tank for further use.

In so cooling the water, however, the usual exhaust blast which induces the draft through the furnace and boiler tubes is lost. To remedy this deficiency a forced draft is supplied by means of a small turbine-driven fan, placed within the radiator or cooler, so that while it serves to cool the circulating water it also induces a blast of hot air to the fire. The cab of the locomotive carries a small switchboard, on which are mounted the controller for grouping the four motors, according to what draw bar pull is required in series or parallel, as well as the regulator for controlling the electrical circuit voltage, and consequently the speed of the train.

The whole of this main and auxiliary machinery is mounted upon a strong underframe, carried on two eight wheeled compound bogies, to facilitate negotiation of curves at high speed. Each bogie carries two of the four driving motors, as already mentioned. It will thus be seen that in reality an articulated system is adopted.

The first engine to be built on these lines is approaching completion, and its performances are awaited with great interest. The experiments which have already been made by the company upon an extensive scale lead them to believe that such a locomotive as this would possess great possibilities and offer a complete solution to the traction question of to-day. In any large well-equipped locomotive establishment an engine can be produced for a low figure in comparison with the electric locomotive, and by the adoption of the new combination they do not anticipate that the prime cost will be very appreciably enhanced.

* * *

The Transvaal government have set aside a fairly large sum for the erection of an experimental scrap iron smelting works. Possibly, says Engineering, the movement may eventually extend so that larger works may be built to deal with the native ore. This ore has already been employed with good results in the manufacture of different articles. Speaking of Pretoria ore, the foreman of the railroad workshops says that it is easily fluxed and good iron obtained free of sulphur and phosphorus. A test of local hematite was recently carried out and 633 pounds of iron was obtained from 1,100 pounds of ore used. The Transvaal mines' consumption of iron and steel is estimated at 59,000 tons yearly, valued at £900,000; of this £600,000 consists of rails, sleepers, pipes and pipe fittings, rock drills, and spares. The railroad also purchases about 22,000 tons of rails and sleepers annually. There is therefore scope for the opening of works, but the government mining engineer considers that the provision of blast furnaces must be a matter for private enterprise. Perhaps some day South Africa may take its place among the great manufacturing countries of the world, but that state of affairs is a long way off at present, and for many years that country will have to depend on its gold and diamonds, and in a lesser degree on its agricultural productions.

[illegible]

[illegible] is designed to [illegible] Pennsylvania Rail-[illegible].

[illegible] under the East River to [illegible] Long Island City, has been practically completed.

[illegible] of the Panama Canal have been opened to navigation. This includes the channel from the [illegible] to the Bay of Panama, where the water is forty-five feet deep at mean tide, to the wharves at Balboa. Steamships are using this part of the canal daily.

The number of railway accidents during the year ending June 30th, 1909, was 66,711, or 3,791 killed, and [illegible] injured. This is a decrease in the total number of 6,942, or 972 killed and 5,969 injured, as compared with the number reported in the previous year. Even the reduced figures do not speak very well for the safety on our railroads.

The great railway bridge across the Sioule gorge in France was opened a short time ago. The height of the bridge is 430 feet above the ground. The bridge consists of a continuous girder 40 feet deep, divided into three spans by two intermediate masonry piers 270 feet high. The main span is 470 feet long, and each of the outer spans has a length of 380 feet.

The Public Service Commission has just issued a synopsis of the report of the Interborough Rapid Transit Company, including both the Subway and Elevated divisions, for the year ended June 30th, 1909. The subway carried 237,451,171 passengers at a total expense of $4,547,820—something less than two cents a passenger. The elevated division carried 275,737,974 passengers. The operating expenses on the subway were $4,457,620, and on the elevated $6,199,822.

Arrangements are being made to consider proposals for a fast passenger and mail steamship and train service from London to Australia and New Zealand by way of Canada, and an 18-knot service on the Pacific. The subsidy aid which would have to be given by British colonial governments would be very heavy. The Australian government demurred at first, but has finally agreed to share in the cost, and a conference will meet in London early in the spring to consider the details and apportion the cost.

A new steamship service will shortly be established between New York and Washington, and freight steamships will be in operation by the first of next year. It is estimated that the journey from New York to Washington will take from thirty-six to thirty-eight hours, including stops. A daily service of passenger steamers is in contemplation. The Potomac River serves an immense territory on either side, which is now largely without modern facilities for traveling or sending goods to market. Wharves are being built, and small steamboats will pick up the freight and carry it to the landings of the large steamships. The country on each side of the Potomac is very fertile, the eastern shore of Maryland produced 4,000,000 barrels of potatoes last year. The great difficulty has been to get the produce to market.

The following notes concerning the storage of California or crude oil in concrete reservoirs were recently given in Concrete. A 1,000,000-barrel reservoir, lined with concrete, has recently been completed at Port Richmond, Cal., and one of 800,000-barrel capacity is under construction near Bakersfield. The practice is to excavate the earth, which in most fields is a sandy loam, porous and very dry, to about one-third the depth of the proposed reservoir. With the material removed, a levee is built round the excavation, having side slopes of 1 : 1½ on both faces. The bottom and sides are then covered with about 3-inch concrete, often reinforced with expanded metal or some equivalent. Small cracks that occur at the junction of the sides and bottom and along the line between the cut and the embankment soon become filled with sediment and are believed to permit the leakage of very little oil. A number of such structures in southern California have recently been examined, and no signs of depreciation in the quality of the concrete were found.

The recent deplorable mine accident at Cherry, Ill., in which there were hundreds of deaths, brings up the question of expert direction in such disasters. Untrained rescuers are entirely useless, as was demonstrated in France a couple of years ago, when [illegible] went down in a mine to [illegible] the expert rescuers from the West-[illegible] by the Kaiser, with their [illegible] too late, but their [illegible] been called in [illegible] number. SCIENCE.

Dr. Percival Lowell is installing a 12-inch telescope on San Francisco Peak at an altitude of 12,000 feet. Prof. V M. Slipher will have charge of the task of erecting the big telescope.

The discovery of a new Alhambra at Ronda, south Spain, by Lawrence Perin of Baltimore is reported. Mr. Perin recently purchased the well known Casa del Rey Moro, and proceeded to make excavations. He found large numbers of Roman and Arabian gold coins and revealed vast galleries.

The Italian Parliament will soon be called upon to provide for a special department to unroll and decipher papyri discovered at Herculaneum. It is trusted that this action may be taken immediately. Some previous documents have been damaged irrevocably because of legislative delay and neglect.

The American Museum of Natural History is to use designs of the famous Mitla ruins of Mexico for the new restaurant which is now being planned. The Mitla ruins were built of adobe and stone ornamented with mural painting and mosaic work produced by stones set in cement. The restaurant will therefore serve the purpose of an exhibition hall.

Some time ago it was ascertained that radium emanations were absorbed by the surface of lungs and intestines, but not by the skin, at least under ordinary conditions. The greater part of the absorbed emanation is quickly eliminated by the lungs, a small part passes away with fecal matter, and finally some has been found in the liver and the bile, but none is ejected with the urine or perspiration.

An international conference is proposed for the preservation of the fur seal and all marine mammals, including whales, walruses, sea lions, and sea elephants. Some of these animals are now all but extinct, and the government considers it time to formulate an international law for their preservation. The Japanese seem to be the chief offenders, for they have even ventured within the three-mile limit to carry on their work of destruction.

In a new process of keeping eggs in cold storage, 500 eggs are packed in a tin box, and a little calcium chloride is added, to insure dryness. A lid, having a hole 1/5-inch diameter, is then soldered on and the box, with a number of others, is placed in a large iron cylinder, from which the air is then exhausted. By this operation the air and carbon dioxide dissolved in the albumen are removed, as well as the air which surrounds the eggs and fills their voids. The cylinder is next filled with pure carbon dioxide, and a pressure slightly above that of the atmosphere is maintained until the constancy of the manometer indicates that the eggs are saturated with the gas. But as eggs do not keep well in pure carbon dioxide, a certain quantity of this gas is next withdrawn from the cylinder and replaced by nitrogen, obtained either from the cylinders in which it is sold in a compressed state or by passing air over red-hot copper. When the eggs have become saturated with the mixture of gases, the boxes are removed from the cylinder, sealed, and placed in rooms where the temperature is kept between 32 and 36 deg. F. By this process the eggs are kept in an atmosphere which contains no free oxygen, and in which the proportions of carbon dioxide and nitrogen are the same as exist in the albumen of fresh laid eggs.

Whether or not there is a planet beyond Neptune is a problem which has long concerned mathematical astronomers. Among those who have taken the trouble mathematically to settle the problem of such a planet's existence is Prof. W H. Pickering, who used the method of Leverrier, the discoverer of Uranus. Prof Pickering believes in the existence of at least one such planet, which he has designated by the letter *O*. A search for this planet was recently undertaken by the Rev J H Metcalf with his 12-inch doublet, but without success. The reasons adduced in Science by Prof. Pickering for this failure are the following: (*a*) The planet may be unexpectedly faint, or reddish in color. Its computed magnitude is 13.5. (*b*) The orbit may be highly eccentric, the computation being based on an approximately circular orbit. (*c*) The orbit may be highly inclined to the ecliptic, and the planet at present situated far from its node. For various reasons the first two causes are not thought sufficiently effective to interfere with the discovery of the planet. We might, by analogy, compare planet *O*, on account of its relative size and position with regard to the other planets, to the sixth or seventh satellite of Jupiter. The inclinations of the orbits of these two bodies are 28 deg. and 28 deg., respectively. The region already covered in the photographic search extends along the ecliptic for 25 deg., and reaches to a maximum distance of 10 deg. to the north and south of it. It is expected therefore to make an examination of the higher latitudes next year. The number of stars already examined in the search is estimated at about 200,000.

AERONAUTICS.

Recognizing that all the leading European nations are rapidly developing aerial fleets of both lighter-than-air and heavier-than-air machines, Gen James Allen, the chief signal officer of our army, made an especial plea in his annual report to the Secretary of War last week for a definite plan of aeronautical development in the army. It is to be hoped this will be given the attention it deserves. Our War Department was the first to order an aeroplane, and it should not fall behind now in aviation or aerostatics.

The second week in December is noteworthy from the fact that Maurice Farman, a brother of Henry Farman, started to make the first cross-country tour ever attempted by aeroplane. Leaving Buc, near Versailles (France), at 2 52 P M December 9th, he arrived at Chatres (42 miles distant) in 53 minutes flying over Trappes and Rambouillet *en route*. His biplane, which resembles that of his brother averaged 47 miles an hour in making this flight. The weather was fine, there being scarcely any wind. The flight formed the first stage of a trip to Bourdeaux, which M Farman hoped to complete in four or five additional flights.

The Wright Company has recently been incorporated in New York for the manufacture of the Wright aeroplane in the United States. The company is capitalized at $1,000,000, Wilbur Wright being president and Orville Wright vice-president. Among the directors are such men as Cornelius Vanderbilt, Howard Gould, and August Belmont. The company will erect a factory at Dayton, Ohio—the home of the Wright brothers—and will also have an aviation field where purchasers can be taught the operation of the machines. It is expected that many American sportsmen will soon become interested in aviation and own aeroplanes.

On the 8th instant Earl Gray, Governor General of Canada, Lord Lacelle, and several other prominent Canadians visited Dr A. G Bell's laboratory at Beinn Behreagh, near Baddeck N S and, in the absence of Dr Bell, were shown about by Messrs. Baldwin and McCurdy, who are still associated with him in his experimental work. A demonstration was given of a new hydroplane boat which rose completely out of the water in a short run of a few hundred feet. It is expected to use this boat beneath an aeroplane, so as to make possible the ascent from water. Despite a hail storm and a soggy field Mr McCurdy treated the visitors to a flight of a mile in the "Baddeck No 2" the second biplane that he and Mr F W Baldwin have constructed this year, and the one with which a considerable number of successful flights have been accomplished. Altogether, there are a half dozen different heavier-than-air machines ready to be tried out on the ice of the Bras d'Or lakes at Baddeck this winter.

The first tests in the United States of firing at balloons were carried out at the Sandy Hook proving grounds on November 27th when a small 3-man captive balloon was anchored at a height of 300 feet and fired at from a distance of 2 000 yards. Fifteen shots were fired from a special 1 pounder having a range of movement from horizontal to vertical, without hitting the balloon. A larger field gun that could be elevated to about 40 degrees was also tried with smoke-producing shells, several of which passed over and several below the balloon. A third kind of shot was a shrapnel which exploded at a certain set distance, and discharged backward a score or more of balls in a widely expanding cone. The balloon was brought to earth by one of these shot. Before the completion of the tests, which lasted several days, 90 shots were fired with but 3 hits. Two of these were without effect. As a result of the tests, army officers believe it will be almost as difficult to hit and destroy a dirigible balloon as an aeroplane.

At the meeting of the Aeronautic Society on December 2nd, Dr Spratt of Coatesville Pa., an intimate friend of Mr Octave Chanute and an aeronautic experimenter of many years' standing, gave a brief talk upon his work in connection with the aeroplane. After calling attention to the fact that all animals walk or move over the ground irrespective of the number or length of their legs, just the same as all flying creatures navigate the air no matter what the size or shape of their wings, Dr Spratt said he believed flight depended upon a general principle as simple as that of the lever which governs walking, but that man had difficulty in discovering this principle since he was not making use of it universally, as in the latter case. Of late years he has devoted himself to finding this principle, in which quest he believes he has met with success. As a result, he has lately applied for a patent upon an aeroplane in which it is embodied. He spoke of having discovered in his early experiments the curve now used on the Wright biplane surfaces. At the suggestion of Mr Chanute the Wrights made quantitative tests of surfaces having this curve and, finding it satisfactory, adopted it. Dr Spratt was with the two brothers three seasons at Kitty Hawk and was an interested witness of their first flights with a motor.

THE NEW PENNSYLVANIA RAILROAD ELECTRIC LOCOMOTIVES

It is a curious instance of what might be called the vagaries of mechanical evolution that the latest and most powerful electric locomotives, of which we present illustrations should be furnished with those side rods and connecting rods, the abolition of which from the electric locomotive was considered to be one of its principal points of improvement.

Theoretically to get rid of the reciprocating movements and unbalanced rotating weights of the steam locomotive was eminently desirable for these unbalanced weights were the cause of much destructive wear upon the track and roadbed Furthermore the substitution of the compact electric motor encircling the driving axle was considered to be an ideal arrangement of compactness and efficiency

When the electric drive came to be applied to steam railroads as in the case of the electrification of the New York Central and the New Haven roads it was found that the above mentioned advantages were obtained at the expense of collateral disadvantages of a very serious character, for the low center of gravity the rigid wheel base, and the large amount of non spring supported weight combined to make the locomotives very destructive of the track Both locomotives met with serious accidents the former bursting open the track on a curve near Woodlawn and the latter doing the same thing when hauling the White Mountain express at high speed through Greenwich Connecticut The running of both types of locomotive has since been greatly improved by the substitution of four wheeled leading trucks on the New York Central locomotive and the introduction of pony trucks on the locomotives of the New Haven road.

In designing the locomotives to be used in the New York tunnel extension of the Pennsylvania Railroad, the engineers of the railroad company and of the Westinghouse Electrical Manufacturing Company have profited by the valuable experience of the past few years, and have designed an engine which will have the high center of gravity and flexibility of wheel base which characterize the steam locomotive It consists of two duplicate sections The wheel plan of each section is the same as that of the old eight wheel American steam locomotive and consists of four coupled drivers and a four wheeled truck

The sections are permanently coupled back to back by a special arrangement of Westinghouse friction draft gear and levers so that the leading section effectually pilots the rear one This obviates all necessity of turning the engine which runs equally well in either direction All manipulating levers are duplicated in each section so the operator simply changes ends.

The most original feature of this engine at least in American practice is the removal of the motors from the wheel axles and the substitution of a single motor which is placed above the frames and within the cab This motor weighs without gear 45 000 pounds and in weight and power it is the largest railway motor ever constructed At each end of the rotor shaft is a crank, the two being set as in steam locomotive practice, at ninety degrees. From these cranks a pair of coupling rods lead down to a crank-shaft (known as a jack shaft) which is carried in the frame in a horizontal line with the axles of the driving wheels. The jack shaft cranks are coupled to the drivers.

Now it will readily be seen that this arrangement avoids all the difficulties of counter balancing which have been such a nightmare to the steam locomotive designer and to the track superintendent for since the motor crank revolves uniformly and at constant effort differing therein from steam practice the turning effort of the drive wheels is the same as for the motor and is constant throughout each revolution Moreover, it will be seen that since the movements of all rods and moving parts are those of pure rotation only, it is possible to secure perfect counterbalance, and the engine delivers no more shock to the track and roadbed than a passenger car of equal weight.

The motor and massive side frame, the jack shaft, and all other gear, are spring supported from the driver and truck wheels, so that there is no track stress other than that local to a single pair of wheels In this arrangement of motor support and connection, the center of gravity height closely approximates that in the best high-speed locomotives.

One of the 2,000 horse-power motors of the Pennsylvania electric locomotives.

A decided improvement in the "Pennsylvania" type is the use of a single motor for two pairs of drivers and the benefits secured by its position. The motor is located high up from the roadbed secure from snow dirt and water, and its design embodies electrical features never before secured on an electric locomotive

The first twenty four locomotives to be built will have the following dimensions

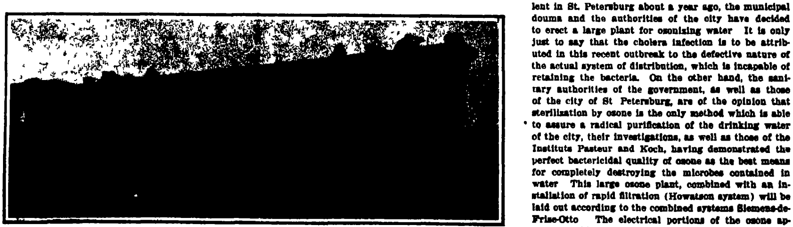
Total weight 166 tons, total horse-power 4,000 maximum draw bar pull 60 000 pounds maximum speed, 60 to 70 miles per hour under load, diameter of drive wheels 68 inches diameter of truck wheels 36 inches, weight on drivers, 104 tons, length over all 65 feet, total wheel base 56 feet.

Drive wheels, 68 inches diameter Truck wheels, 36 inches. Length over all, 65 feet.

Chassis of the new electric locomotive.

The controller on the "Pennsylvania" type is scarcely as large as that on a Hoe printing press None of the main power passes through it, as it is really a switch corresponding to a telegrapher's key operated by electro-pneumatic means. With a lever which can be moved with one finger, the engineer can admit to the locomotive a current equal to that available in a hundred trolley cars

The electric supply will be secured from an electric conductor, or third rail, by four contact shoes on each locomotive At some points where the great number of track switches will not permit this power will be secured from an overhead conductor through an air-operated overhead contact shoe, of which there are two on each locomotive. The first locomotive, which is now being tested both as to speed and hauling power on the Long Island Railroad, is giving satisfactory results.



Weight, 166 tons. Horse-power, 4000 Drawbar pull, 60,000 pounds.

THE NEW PENNSYLVANIA RAILROAD ELECTRIC LOCOMOTIVE

Electric Traction in Tunis.

In the region of Tunis there has been installed an extensive system of electric traction lines. The new electric sections, which are now in regular running, are designed to replace the former steam railroad. This latter comprised three lines, one of these running from Tunis to La Goulette, about 10 miles distance, the second from the city to Marsa, 11 miles, and the third from La Goulette to Marsa, about 5 miles. The region covered by the lines is of interest as being the site of ancient Carthage and its extensive suburbs. The first two sections had a common portion of about 6 miles between Tunis and Aouina. The steam lines had been conceded in 1871 to an English company which turned them over to the Florio Rubattino company ten years later, and they afterward passed into the hands of the Bone-Guilma railroad company The government made an arrangement in 1905 with the Tunis traction company to have the lines changed to the electric system. This was carried out by the Paris Thomson Houston firm, and the government wished to profit by the jetty which had been laid across the Tunis Lake so as to use it for the line as far as La Goulette and thus run in a straight path The old traject is kept between La Goulette and Marsa, but there is also a second branch which runs nearer the sea coast, traversing the site of Carthage and reaching the elevated locality of Sidi bou Saïd, then descending to the terminus at Marsa.

The object of the new line is to enable the population of Tunis to reach the seashore easily and rapidly, and the new shore branch could not be realized by the steam road on account of the irregular ground covered here It is expected that the suburban region will be much more developed by the use of the electric line. At present the trains are made up on the multiple-unit system of two motor cars and from one to three trailers The motor cars are fitted with two motors of the G E-66 type which run on 600 volts on the overhead wire or third rail, and give 125 horse-power, using two series-parallel controllers With front and rear motorman's cabins the cars have first and second-class compartments and also a baggage or light freight compartment. The chassis has two bogies, one of which carries the motors. Current is taken by third rail for the suburban part of the line, and it is only within the city that the trolley is used The motor cars weigh 28 tons and contain 100 places, while the trailers, of an equal capacity, weigh 22 tons

The Great St. Petersburg Ozone Plant.

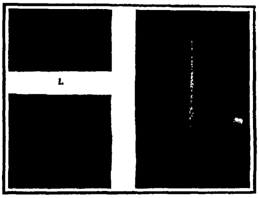
In view of the very satisfactory results obtained by the purification of the water of the Neva in ordinary sand filters, when the epidemic of cholera was prevalent in St. Petersburg about a year ago, the municipal douma and the authorities of the city have decided to erect a large plant for ozonizing water It is only just to say that the cholera infection is to be attributed in this recent outbreak to the defective nature of the actual system of distribution, which is incapable of retaining the bacteria. On the other hand, the sanitary authorities of the government, as well as those of the city of St Petersburg, are of the opinion that sterilization by ozone is the only method which is able to assure a radical purification of the drinking water of the city, their investigations, as well as those of the Instituts Pasteur and Koch, having demonstrated the perfect bactericidal quality of ozone as the best means for completely destroying the microbes contained in water This large ozone plant, combined with an installation of rapid filtration (Howatson system) will be laid out according to the combined systems Siemens-de-Frise-Otto The electrical portions of the ozone apparatus will be constructed by the Siemens & Halske Company and the plant of Felten Guilleaume-Lahmeyer.—La Nature.

THE LIFE OF A SPLASH.

BY PERCY COLLINS.

Probably many people have at times watched the splashes caused by rain drops falling upon the smooth surface of a pool or river. Some, too, may have gone so far as to differentiate between the splashes formed by the big drops of a thunder shower and those produced by the smaller drops of a gentle rain. In the former case a conspicuous bubble floats for a moment, and then vanishes, in the latter a crystalline fountain seems to start from a surrounding coronet of lesser jets—though this is in part an illusion, for it is known that in reality the coronet has vanished before the jet appears. The image of the coronet has not had time to fade from the eye ere that of the jet is superposed upon it. Moreover, it may have chanced to the reader to note the different effects, both of sound and of splash, produced by a stone dropped into the water—these differences apparently depending upon the height from which the stone descends, and upon the condition of its surface, i. e., whether it is smooth or rough, wet or dry. But if the reader has at one time or another made such naked-eye observations of splashes, it must be clear to him that while he has seen something, he must also have missed seeing very much more. For a splash, no matter in what way it may be produced, consists in the progress of a multitude of events, compressed within the limits of a few hundredths of a second but none the less orderly and inevitable, and of which the sequence is in part easy to anticipate and understand while in part it taxes the highest mathematical powers to elucidate.

Some fifteen years ago, Prof. A. M. Worthington, C.B., F.R.S. (Head Master of the Royal Naval Engineering College, Devonport, England), commenced a systematic study of splashes, and in order fully to appreciate the disturbance of the liquids with which he experimented and their relations he invoked the aid of photography. In these days of kinematographs and rapid snap-shot cameras, it might seem an easy matter to follow, by means of photography, even a splashing drop. But if the reader harbors this thought, he has failed to grasp the extraordinary rapidity of the movements which take place. As Prof. Worthington reminds us, the problem of how to photograph a splash is by no means a simple one, for the changes of form that take place are far too rapid to come within reach of any ordinary kinematograph, while the quickest photographic shutter is also much too slow. Thus, it became necessary to have recourse to the far shorter exposure of an electric spark. It was found that the bright spark given by breaking the primary circuit of an induction coil at the surface of mercury was of much too long duration to be useful for the purpose of flash photography, so that the originals of the photographs reproduced on this page (for which we are indebted to the courtesy of Prof. Worthington) were taken by means of a spark the duration of which was certainly less than three millionths of a second—a period of time which bears to the whole second about the same proportion as a day to a thousand years.



1 Primary column succeeding a drop into running water. 2. Column succeeding a drop into still water. Time 0.19 second each case. 3. Primary column caused by a rough sphere falling into liquid.

This flash is obtained by charging two Leyden jars by an electrical machine on their inner coats, one positively and one negatively. Stout wires lead from the outer coats to the dark room (where the splash is to be photographed) and terminate in a spark gap between magnesium terminals and close over the surface of water contained in a bowl. The inner coats of the Leyden jars being now connected together the positive and negative charges unite in a dazzling flash and a simultaneous discharge and flash take place between the two outer coats across the spark gap in the dark room. This latter is the illuminating spark, by means of which the photographic exposure is to be made. The exact timing of this spark is obviously of the greatest importance. This is effected by means of a falling metal sphere which passes (outside the dark room, of course) between two terminals connected one with the inside of one Leyden jar and one with the inside of the other. These terminals are just too far apart for a spark to jump across till the timing sphere passes between them. But when this occurs the discharge takes place with the accompanying flash in the dark room. By means of an ingenious arrangement of magnets and springs (for full details of which the reader is referred to Prof. Worthington's work ("A Study of Splashes") the timing sphere can be made to fall either simultaneously with the drop or sphere destined to cause the splash to be photographed or slightly earlier or later. In this way it is possible brilliantly to illuminate the splash for one three-millionth part of a second at any desired period of its progress. For example, if a particular stage of the splash is photographed when the timing sphere falls just four feet to the gap between the terminals, then by raising its releasing lever about two-fifths of an inch the law of falling bodies insures that the flash will be postponed by just one thousandth of a second and the next photograph accordingly reveals a stage just so much later.

From these brief particulars the reader will be able to form an idea of the way in which Prof. Worthington's photographic studies of splashes are obtained. The camera being previously focused and arranged in the dark room, the timing sphere is minutely adjusted and released and a record of any desired period of the splash is obtained upon the sensitized plate. Yet despite the rapidity of the plates employed and the brilliancy of the flash, the duration of the illumination is so short that the negatives are always under-exposed. Hence tedious precautions have to be taken in their development.

We may now glance rapidly at a few of the many interesting facts which have been established by Prof. Worthington's study of splashes. It will probably surprise the reader to learn what a lengthy series of events follows the contact of a small drop of water, falling from a height of about 16 inches into a mixture of milk and water, the milk being added to render the photographs more intelligible. First, as the drops strikes and penetrates the surface there arises a crater, which rapidly increases in size until upon

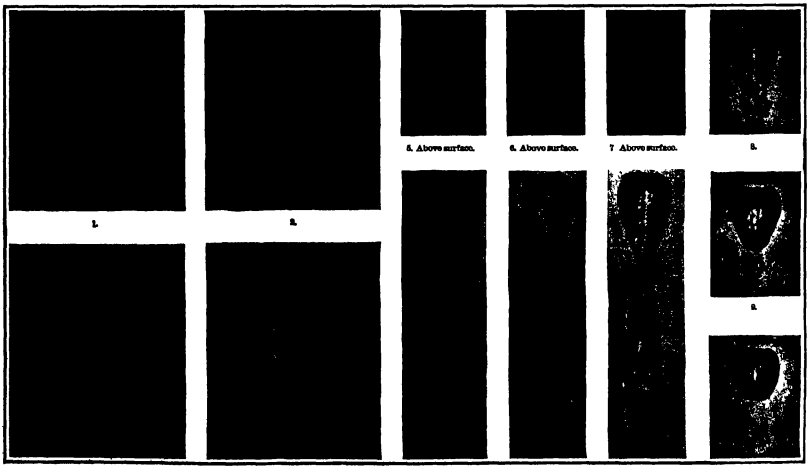
The phenomena of a drop of water falling 40 centimeters into water.



THE VARIOUS STAGES OF A SPLASH PRODUCED BY A ROUGH SPHERE FALLING 800 CENTIMETERS (26.3 FEET) INTO WATER.

Prof. Jonnesco and Spinal Anæsthesia.

The visit of Prof. Thomas Jonnesco to New York has brought prominently before the public the method of producing local anæsthesia by the injection of anæsthetic solutions into the spinal canal.

Cocaine was introduced years ago as an anæsthetic for local application. It was welcomed by the medical profession, and equally by patients, on account of its invaluable services in operative procedures upon the eye, the nose, and the throat. By merely placing a drop or two of a solution of cocaine (or one of its salts) into the eye, or by painting a similar solution upon the mucous membrane of the nose or throat, it is possible to produce anæsthesia so complete as to enable surgical operations to be performed upon these parts without inflicting the least pain or discomfort upon the patients. Certain objections to the use of cocaine were not long, however, in showing themselves. Cocaine is a powerful alkaloid, and if the usual dose be exceeded, very grave results follow, a number of patients having actually died as the result of cocaine poisoning. Investigators were therefore led to search for other substances, either like cocaine occurring naturally, or prepared synthetically, which would possess the properties of cocaine while being less poisonous.

In this way, states Nature, a number of anæsthetic drugs have been introduced, including alypin, holocaine, eucaine (alpha and beta), scopolamine, novocaine, stovaine and tropacocaine. Of these the three latter have been chiefly employed in producing spinal anæsthesia. The method consists in injecting, by means of a syringe and needle, a quantity (usually about one cubic centimeter) of a solution of one of these substances into the spinal canal. The injection is made in the back, close to the middle line, the needle being inserted between two of the vertebræ. With regard to the details of the method, various procedures have been described, and no agreement has yet been reached as to which of these is to be considered the best. There is no doubt that modifications are desirable to suit particular requirements. Thus, many operators direct that the drug be dissolved in cerebro-spinal fluid or else in a saline solution having the same specific gravity and the same osmotic tension as the blood-serum. Others consider that the anæsthetic solution should be considerably denser or more viscous than the cerebro-spinal fluid, and for this purpose recommend the addition of glucose or of gum-acacia to the solution. These thicker solutions tend to remain at the spot at which they are injected, while solutions in cerebro-spinal fluid or in normal saline tend to spread up and down the spinal canal, and thus have a more widespread anæsthetic effect. It is usual to withdraw a few cubic centimeters of cerebro-spinal fluid from the spinal canal before injecting the anæsthetic fluid. There are two reasons for this—first, the surgeon is assured that he has actually introduced his needle into the spinal canal, and secondly he is certain to avoid increasing unduly the cerebro-spinal pressure when he introduces the anæsthetising fluid.

On introducing the fluid into a particular part of the spinal column, anæsthesia is produced of all parts of the body deriving their nerve supply from this part of the spinal cord, and all parts below. If the fluid be allowed to ascend the spinal canal (e. g., by raising the hips) the anæsthesia rises higher and higher as the anæsthetic fluid reaches the trunks of the nerves arising from the higher parts of the spinal cord. If the patient be placed on one side while the injection is being performed, the anæsthetic fluid can be made to enter one lateral half of the spinal canal, and in this way it is possible to limit the anæsthesia to one lateral half of the body.

The anæsthetic fluid can be allowed to ascend almost to the top of the thoracic spine without fear of untoward consequences. When it reaches the base of the neck, however, the phrenic nerve, concerned with the movements of respiration, becomes involved, and it was deemed impracticable to produce anæsthesia of the head and neck by the spinal method. Prof. Jonnesco, however, has shown that the addition of strychnine to the anæsthetic solution produces so powerful a stimulant effect upon the respiratory center in the brain that it is possible to introduce an anæsthetic fluid into the upper part of the thoracic spine, and to allow the fluid to ascend the spinal canal in the neck so as to enable operations to be performed on the neck and throat. But it is as yet too early to say whether this method may be considered a safe one.

Of the three drugs which are now chiefly used for the production of spinal anæsthesia, stovaine is found to produce the most deleterious effect upon the kidneys, acute nephritis having followed its injection in quite a number of cases. Novocaine and tropacocaine are less injurious in this way, while they are equally efficacious as anæsthetics. It thus appears likely that they will supplant stovaine in the near future, and, in fact, tropacocaine in a one per cent solution is already being largely used for the purpose in this country, the usual dose injected being about 1¼ grain.

No doubt further experience will lead to modifications in the present method of performing spinal anæsthesia which will [illegible] there are a [illegible] thetic is far more [illegible] surgeon than is general anæsthesia.

A SIMPLE AND EASY METHOD OF MEASURING THE HEIGHT OF AN AEROPLANE ABOVE THE GROUND.

The vertical plane in which the height of the aeroplane above the ground is to be taken, is determined beforehand and marked on the ground by two stakes sufficiently far apart and long enough to allow the two observers commissioned to take the measurement to note the precise moment when the aeroplane comes into the plane determined by the two stakes.

The base $O_1 O_2$, or line of this plane on the ground, is carefully measured and with as much precision as desired. This can be any desired length, say 500 feet. At O_1 and O_2 two observers are placed, each provided with a theodolite-like instrument, or any other apparatus used in artillery for measuring the angles α and β made by the straight lines $O_1 M$ and $O_2 M$ with the base $O_1 O_2$. This measurement must be taken simultaneously by the two operators at the precise moment the aeroplane crosses the vertical plane $O_1 A B O_2$. This much given, we purpose determining the height of M or h. a simple examination of the diagram shows that we can write

$$O_1 m = h \cot \alpha$$
$$O_2 m = h \cot \beta$$

Adding these two equations, member to member, we have

$$h\ (\cot \alpha + \cot \beta) = O_1 m + O_2 m = O_1 O_2$$

Whence

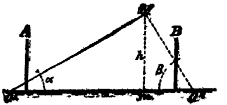
$$h = \frac{O_1 O_2}{\cot \alpha + \cot \beta}$$

If the angle measuring apparatus is graduated and gives directly the lengths of the cotangents, we shall have, supposing $\cot \alpha = a$ and $\cot \beta = b$

$$h = \frac{500}{a + b}$$

It is easy to see that with a slide rule a simple reading will immediately give the value of h.

Instruments for measuring angles α and β are so well known in artillery that it is unnecessary to refer to them; but we will remark that this method of measuring is susceptible of great precision and should give satisfaction not only to the aviators themselves but also to the official observers.



MEASURING THE HEIGHT OF AN AEROPLANE.

Although altitude trials are not made often, the writer hopes, in the near future, to make some height measurements by this method, with the help of a very ingenious apparatus that measures the angle and at the same time determines the plane.—A. Boyer-Guillon, C.E., in L'Aerophile.

A Novel Science Entertainment.

Mr. H. Snowden Ward of Hadlow-Kent, England, is giving a new science entertainment on the plan of Prof. Pepper's and others entitled "The Marvels of Photography." After a brief explanation accompanied by a few pictures of the developing tanks, by means of one brilliant light the audience is photographed simultaneously with several cameras directed to various parts of the hall. Two very large prints are made on developing-out paper in full view of the audience.

An assistant at the same time makes natural color exposures with autochrome plates on a special subject, and also transparencies from the regular negatives of the audience. The immense paper prints of the audience are then displayed, and later the transparencies and color pictures are projected by a lantern upon a large screen. Under the auspices of the Camera Club of New York, this entertainment is to be given in this city during the winter by Mr. Ward.

The [illegible] taining articles too long for insertion in the SCIENTIFIC AMERICAN, as well as translations from foreign periodicals, the information contained in which would [illegible]

[illegible] We have [illegible] the [illegible] front-page illustration, [illegible] ponderous heap, they would [illegible] last crops were piled up in [illegible] the Metropolitan Tower. [illegible] and many blocks surrounding it would be [illegible] lost under the mass of cereals [illegible].

The corn, which is the [illegible] shown, is represented as [illegible] up in pillars so as to [illegible] and though the pillar reach up to a height of [illegible] feet, this year's production of corn would [illegible] of these pillars. Next to the corn we have the production of oats, amounting to a huge total of [illegible] billion bushels. The huge bag containing this quantity of oats would reach up to more than [illegible] the height of the Metropolitan Tower. The wheat, which comes next in order, would require a bag [illegible] large which, even when laid on its side, would overtop the tallest structures in New York. If this wheat was distributed among the inhabitants of this country, every one, man, woman, and child, would receive over eight bushels for his share of the crop. If this quantity were taken to a flour mill, it would be converted into one and two-thirds barrels of flour, and out of this quantity of flour a baker could make nearly five hundred loaves of standard five-cent size. In other words, we grow enough wheat in this country to supply every individual with a loaf and a half of bread per day. This is slightly more than the average supply per capita for the last forty years.

Comparing our crops with other countries, we find that the United States leads the world in the production of corn, oats, and wheat. Last year [illegible] not equal European Russia's oats production, but this year's estimate is 173,[illegible] bushels more than that of last year; and while the figures for the 1909 crop in Russia are not as yet available, it seems improbable that they will equal our own figures for this year. When it comes to barley, we must take second place, according first place to Russia. Russia also leads the world in the production of rye. We stand fourth in the production of potatoes, with Germany, Russia, and Austria ahead of us.

While we may flatter ourselves on our production of corn, oats, and wheat, the figures show that we do not make the best use of our acreage. The United Kingdom seems to be able to produce more wheat from an acre of land than any other country. For the years 1898 to 1907 it has produced [illegible] bushels per acre, as against 13.9 in this country and [illegible] in Russia, which makes the poorest showing of the large wheat-growing countries. Germany leads in the yield of oats with 49.3 bushels per acre against [illegible] in this country. However, it [illegible] the country having the [illegible] should have a poorer [illegible] in which farming operations [illegible] scale and more particularly [illegible] the treatment of the land [illegible] product.

The crop estimate [illegible] preliminary estimate, and the [illegible] will be published [illegible] AMERICAN is on the press. [illegible] given below, showing a large increase over last year's figures in nearly every crop.

[illegible]

[illegible]

[illegible] of December 4th, page [illegible] "The Cherry Mine Disaster," [illegible]

[illegible] the accident, the min- [illegible] in some of the gal- [illegible] taken out after their [illegible] to the experts of the [illegible] Commission and of the Technologic [illegible] United States Geological Survey, who [illegible] from the first that there were [illegible] in the mine, and that a day or two [illegible] little difference."

It was with sincere regret that I read such a statement in a journal that has large influence among the [illegible] people of the country. I fear that the statement you make will be largely believed, and that it will [illegible] injury to a movement which gives [illegible] of aiding materially in working out [illegible] of preventing mine disasters, as [illegible] aiding in the rescue work following [illegible]

[illegible] may have been the personal opinion of [illegible] mining experts at the Cherry [illegible] probability of the entombed miners being [illegible] at any time following the disaster [illegible] such opinion was given out or in [illegible] their efforts—which were continued night and day—to reach the entombed miners, [illegible] dead or alive. On the other hand, the mining [illegible] of the government and the members of the [illegible] were not only willing but insistent that the rescue work should go forward as rapidly as possible. Your correspondent's statement also does equal injustice to [illegible] State inspectors, who were doing everything possible to get into the mine with the same commendable purpose in view.

As you may know, the mining engineers of the government are entirely without authority for direct [illegible] rescue work. Their official work is that of investigations as to the causes of such disasters; but they were anxious to and did aid in every possible way in the work of opening up the mine with a view to saving life.

Their use of helmets for artificial breathing while [illegible] mine gas was in several instances effective at this mine, as it has been in saving life at several other mine disasters. Such use of the oxygen helmet has on a number of occasions been of even greater service in preventing mine explosions, and extinguishing mine fires.

George Otis Smith, Director.

Washington, D. C. United States Geological Survey.

[It should be stated that our correspondent, who visited the Cherry mine, and informed himself fully in regard to the situation there, stated that experts of the [illegible] made the statement referred to. Of course, such statements were entirely informal and [illegible], and it was far from the wish of the Editor to [illegible] that any negligence on the part of the [illegible] has occurred. The admirable work of the Geological Survey is too well known to require [illegible] in our columns.—Editor.]

[illegible]

[illegible] decision of far-reaching importance [illegible] has been recently delivered [illegible] House of Lords, which is the [illegible] Alexander Stanley Elmore [illegible] United States, and the company exploiting the [illegible] process for the separation of ore by selective action, proceeded against Minerals Separation Limited, which [illegible] were infringing his [illegible] depended upon the selective [illegible] of their process, but Elmore [illegible] did not achieve [illegible] In the course of experiments he [illegible] that if a small quantity [illegible] the selective action [illegible] and in fact con- [illegible] of the process [illegible] a patent completed [illegible] however, [illegible] was distinctly [illegible] of using [illegible] only used [illegible] Elmore appealed, and the lower court's findings were reversed. Minerals Separation Limited consequently carried the matter to the House of Lords, and this supreme court has now pronounced definitely against the claims of the Elmore patent.

In the course of their judgment the Lord Chancellor stated that the 1901 patent specification was framed with great subtlety, narrative and claim being so closely interwoven as to render it difficult to decide how much of the narrative ought to be read into the claim. Disentangled, however, the specification turned upon the point that Elmore claimed the sole right to add any acid to the solution. No statement is made as to the proportion of this agent, this varying according to the character of the material treated. The Lord Chancellor stated that this latter factor is so wide that it sought to cover any known process of separating mineral substances by the selective action of oil and acid, and stated that he did not consider that Elmore had really discovered the enhanced effect produced by the addition of acid. For this reason he pronounced against the 1901 patent, and decided that no infringement had been made of Elmore's patent, in which decision the four other judges unequivocally concurred. This final decision has terminated a protracted litigation, and the Elmore claim cannot now be possibly sustained.

The Scientific American Aeroplane Trophy.

When the proprietors of this journal gave into the custody of the Aero Club of America their handsome aviation trophy nearly three years ago, it was with the belief that such a cup would help to create interest in the fascinating subject of human flight and would stimulate American inventors to renew their efforts toward its solution. It was at first thought advisable to hold contests upon a given date and at a stated place, and the first such contest was to have been held at the Jamestown Exhibition on September 14th, 1907, but as there was only one uncompleted aeroplane ready at that time, and as the announcement of future competitions did not meet with any response, it was decided to change the rules so that any experimenter could try for the trophy at any place provided he gave a few days' notice to the Aero Club so that the proper officials could be present to time and observe the flight. Under the new rules Glenn H. Curtiss made the required flight of a kilometer in a straight line at Hammondsport, N. Y., on July 4th, 1908, as a result of which he was declared the winner of the first leg of the trophy. Instead of requiring a specified distance for 1909, it was decided to award the trophy this year to the aviator who covered the greatest distance in excess of 25 kilometers over a closed-circuit course. On July 17th Mr Curtiss made a new record of 24.94 miles in 52½ minutes above a triangular course at Mineola, L. I. This is the present record, and is the longest flight made in America by any aeroplane except the Wright. If it remains unbroken up to sunset on December 31st, Mr Curtiss will have won the second leg of the trophy and will have to win it but one more year in order to hold it permanently.

As there are several new aviators who have been making successful though brief flights of late with their own aeroplanes, we believe that it would require but a little practise upon the part of some of these to enable them to surpass the present record. Flying an hour in December, in the vicinity of New York should be no more arduous than automobiling for a like length of time, and when the prize to be won thereby is the first, the handsomest, and the most commemorative trophy ever offered in America, it is certainly well worth the attempt. We look for some budding aviator to send in his entry during the last days of the present year.

Nobel Prizes Awarded.

This year's Nobel prizes will be distributed as follows: For physics, divided between William Marconi and Prof. Ferdinand Braun of Strasburg, for chemistry, Prof. Wilhelm Ostwald of Leipsic, for physiology or medicine, Prof. Theodor Kocher of Berne, for literature, Selma Lagerlof, the Swedish authoress.

The Nobel prizes, which are worth about $40,000 each, are awarded annually to those persons who are considered to have conferred the greatest benefit on mankind during the preceding year in the fields specified in the cable dispatch, with the addition of one for the best effort toward the fraternity of nations and the promotion of peace.

Prof. Ferdinand Braun is Director of Physics at the University of Strasburg. He was born at Fulda, Germany, on June 6th, 1850, and was educated at the University of Berlin. From 1876 to 1883 he was professor at the University of Marburg.

Prof. Wilhelm Ostwald, who received the Nobel prize for chemistry, was born at Riga in 1853. In 1887 he became Professor of Chemistry at Leipsic. As an investigator in connection with physical chemistry and chemical [illegible] he has become particularly well known. His researches have concerned, among numerous subjects, the electric conductivity of organic acids, and the color of ions. He has published several volumes on this and other scientific subjects.

Prof Emil Theodor Kocher, who will receive the Nobel prize for physiology and medicine, is a Swiss surgeon. He is a native of Berne, where he was born in 1841 He was educated there, and after studying at Berlin, Paris, and London became Professor of Surgery in the university of his native city and Director of the Surgical Clinic. His especial field is the thyroid gland.

The Current Supplement.

Mr Robert M. Strong's admirable comparison of the gasoline and alcohol engines is continued in the current SUPPLEMENT, No 1772 Mr Vaughan H Wilson contributes an excellent note on the future of aluminium as a substitute for copper wire. Mr George S Hodgins writes on time speed control signals, in which he explains how the New York Subway trains are automatically controlled In view of the difficulty experienced by the New Theater in New York city with its acoustics, an article by Floyd R. Watson should be of interest. The wonderful wine-growing and wine-pressing establishments of Kempinski & Co., the largest in Germany, are fully described and illustrated Our Paris correspondent writes on the new electric locomotives for the Simplon tunnel Action at a distance produced by drying oils is the title of an article by Werner Schmidt. He shows that many substances apart from radio-active substances affect the photographic plate. Among these is a class of so-called drying oils, the best known of which is linseed oil varnish. Mr William H Ballou contributes a popular article on some of the showy mushrooms in nature In view of the return of Halley's comet, Prof E. E. Barnard's contribution on photographing comets is most valuable.

Daniel's Comet.

Zaccheus Daniel of the Princeton observatory discovered a great comet on December 6 d. 599 Gr M T, in R. A, 6d 16m 30s. Dec. + 33 deg. 50 min with a slow northerly motion. At the time of its discovery the comet was visible in a small telescope.

Prof E. E. Barnard of the Yerkes observatory observed Daniel's comet December 7 d. 6606 Greenwich Mean Time, in R. A. 6h. 16m. 42s. Dec. +34 deg. 44 min 22 sec.

At Smith College observatory, Northampton, Mass., Daniel's comet was observed on December 8 d. 5870 Greenwich Mean Time, in R. A. 6h. 16m 57 6s. Dec. +35 deg 30 min 53 sec.

Metcalf reports Daniel's comet December 8th 1909, at G M. T 12h 30m., R. A. 6h 16m 52.5s. Dec. +35 deg. 27 6 min

Continued Ephemeris of Halley's Comet.

A letter has been received at Harvard Observatory from Father G M. Searle, C.S P, of New York, giving the following "Continued Ephemeris of Halley's Comet. T assumed to be Apr 19 d. 692 G M T '

Official Meteorological Summary, New York, N. Y., November, 1909.

Atmospheric pressure Highest, 30 72, lowest, 29 48, mean, 30.16 Temperature Highest, 74, date, 12th, lowest, 30, date, 25th, mean of warmest day, 62 date, 12th, coolest day, 32, date, 25th, mean of maximum for the month, 54 1, mean of minimum, 41 3, absolute mean, 47 7, normal, 43.9, excess compared with the mean of 39 years, 3.8. Warmest mean temperature of November, 50, in 1902, coldest mean, 37, in 1873 Absolute maximum and minimum of November for 39 years, 74 and 7 Average daily excess since January 1st, 1.0 Precipitation 1 58, greatest in 24 hours, 1 0 date, 24th and 25th, average for November for 39 years, 3.38. Accumulated deficiency since January 1st 4 44. Greatest precipitation, 9.82, in 1889, least 0 75, in 1903. Wind Prevailing direction northwest, total movement, 9,232 miles, average hourly velocity 12 8, maximum velocity, 48 miles per hour Weather Clear days, 11, partly cloudy, 11, cloudy 8, on which 0 01 or more of precipitation occurred 6 Snowfall 1 0 Sleet 23rd, 24th, 25th Mean temperature of the autumn, 53.50; normal 55.27 Precipitation of the autumn, 4.38, normal, 10.57

THE NINTH ANNUAL LÉPINE EXHIBITION OF TOYS IN PARIS.

BY JACQUES BOYER.

This year's Lépine exhibition of toys, like that of last year, contains many toys relating to aviation. Kites of strange designs, aeroplanes, and dirigible balloons are shown in great numbers.

Richer's "Modern War" represents an attack upon an airship, which carries a target consisting of two crossed flags. The projectile, which is shown in the center part of our photograph, is a small aeroplane made of wood and celluloid. It consists of a wooden spindle with a longitudinal slot for the reception of the wings. A screw propeller is attached at the stern. The projectile is launched by means of a pistol, the barrel of which also has a longitudinal slot through which the wings of the aeroplane pass. When the target is struck the balloon separates into two parts, as shown in the illustration.

The "Roulis-Bilboc" of the same inventor is a little billiard table mounted upon a spherical joint, which allows it to be turned and tipped in every direction. By the side of the table is a vertical support, on which slide three wires terminating in hooks, from which three balls are suspended at a determined height above the table. The game is played by means of a top, the upper part of which is hollowed out to form a hemispherical cup of a diameter equal to that of the balls. The player winds the top and sets it spinning on the table, which he then moves in such a manner, by means of the lever, as to bring the top directly under one of the three suspended balls, and then tips the table so as to catch the ball in the cup and remove it from its support.

The "Avion" and the "Mechanical Birds" of Le Dantec are aeronautic novelties. The "Avion" is supported, propelled, and steered entirely by screw propellers driven by turbines. The "Avion" itself is formed of an assemblage of metal tubes which support a horizontal frame. This frame carries two horizontal propellers for support and ascension, and three vertical propellers, one for propulsion at one end of the axis of the [illegible] and two for steering at the other end, the axes of these being at right angles to that of the large one. Above this frame is a plane surface having two circular openings immediately above the lifting propellers, and four valves in the form of rectangular doors, hinged at their front edges, which open and allow the air to pass during the ascent of the "Avion," but close as soon as it begins to fall. All of these propellers are driven by explosion turbines of a type invented by M. Uhlenhuth.

The "Fil-Vit" is a self-starting aeroplane, three forms of which are shown in one of the photographs. Part of the flight is accomplished by means of screw propellers driven by stretched rubber bands, the other part by soaring. One of the types is a Wright biplane with two propellers at the bow. It rises from the ground by its own effort, and accomplishes a flight of fifty yards. Another is a monoplane with one bow and one stern propeller, which also rises unaided and flies fifty yards. The third is a biplane with two bow propellers, which rises after running two yards on the ground and makes a flight of one hundred yards, gradually rising to a height of five yards.

Blin's "Crossing the Channel" is a simple but novel and attractive racing game. Starting from the French coast as Blériot did, the aviators, represented by little paper figures, endeavor to reach the cliffs of England. The aeroplanes are attached to elastic cords, which are stretched between pulleys on the two coasts. Each player, by turning his pulley, causes his aeroplane to advance, but also produces vibrations which frequently result in a fall into the sea, which for the sake of realism is dotted with little vessels.

The "Aigleplan" is simply a large kite representing an eagle. The frame is formed of whalebone, steel and bamboo. The wings and head of the bird are rigid planes, and the body is represented by four rectangular pieces of very stiff canvas. The lifting power of the kite is sufficient to make it available for experiments in aerial photography and wireless telegraphy, and the constructor, M. [illegible], uses it for advertising purposes. The largest of these kites can carry a [illegible]

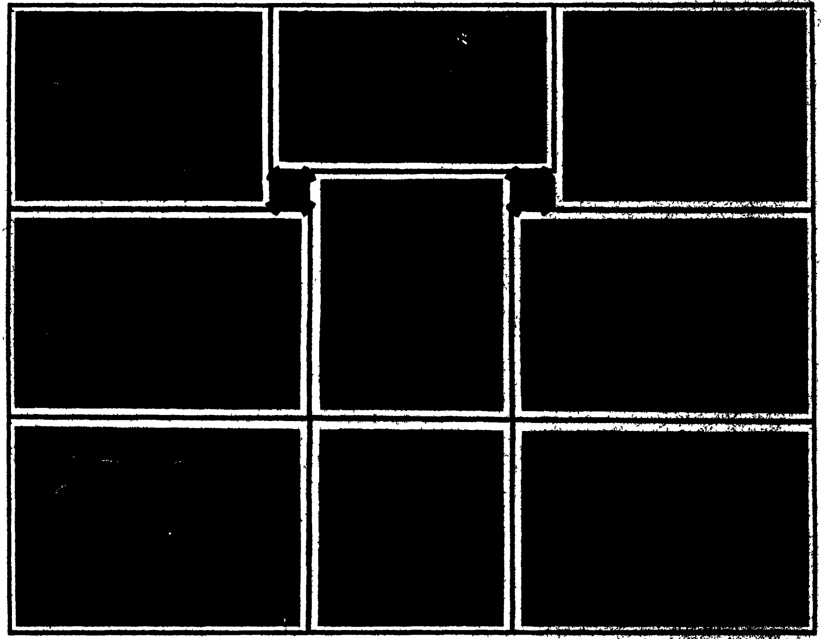
[illegible] have [illegible] the Paris [illegible].

[illegible] "Whirlwind" is [illegible] curved [illegible] in which a car moves. The [illegible] the left of Fig. 1) is a [illegible] resting upon four springs, which can be depressed more or less by pulling a cord. On the platform is placed a ball, which, by operating a cord and thus tipping the platform, is caused to strike and knock down little puppets, seated on benches around the edge.

Blin's "Polar Billiard Table" represents, in relief, the scene of the recent exploits of Cook and Peary. The North Pole is represented by a small depression. The convex polar region rests upon a square table with a raised edge. The game is played by four persons, and consists in pushing a pith ball, with the aid of a thin wooden blade, up the convex surface and into the hole at the pole. The rotundity of the surface and the flatness of the blade combine to make this feat more difficult than it might appear.

There are some of the most [illegible] to be seen at the Ninth Lépine exhibition [illegible]

[illegible]



1. The "Mechanical Bird" and its propeller 2 The Flight Across the Channel. 3. The "Fil-Vit." 4. The North Pole Game. 5. "Modern War." 6. The "Whirlwind." 7. The "Avion." 8. The "Aigleplan." 9. The "Roulis-Bilboc."

STRIKING TOYS AT THE NINTH ANNUAL LÉPINE EXHIBITION, PARIS.

[illegible] PLANTS OF THE FUTURE.

[illegible] by scientists as beyond dispute [illegible] among plants is more widespread [illegible] was formerly supposed to be. The species [illegible] (Droseraceae) are but the advance guard of a large army of species which depend for their existence more or less upon the absorption of animal food through their foliage. There is no gainsaying the statement, recently put forward by more than one scientist, that the tendency to rely upon a carnivorous diet is on the increase. Of course this is only in line with the simplest evolutionary principle. It is possible to trace the steps by which the highest types of species, which seize and hold their prey such as the Venus fly trap (Dionaea) have been evolved from those which merely capture their victims by the use of an adhesive fluid such as the fly catcher of Portugal (Drosophyllum). Still lower in the scale are the plants, such as the teasles (Dipsacus) which drown the insects in strange bucket-like contrivances located at the base of the leaves. Flies which may chance to fall into the water are of course drowned and the plant absorbs the nitrogenous elements from their decaying bodies.

It is a startling conception that in ages to come the plant world as a whole may become so advanced in carnivorous tastes as to be a real menace to animal creation. Dreadful indeed must be the sundews and the Dionaeas to their insect victims at the present time. The unfortunate fly which is captured by the leaf of the sundew finds itself held down by strong arms which are able to resist its violent struggles. The largest Droseras on earth at the present time produce leaves which are perhaps nine inches in length. Magnify this plant until the leaves are ten feet in length and we have an exceedingly formidable specimen. Many of the palms and other tropical species have foliage which is much in excess of this measurement, so that the idea of leaves as big as this is not altogether fantastic. To be in proportion the tentacles could scarcely be less than ten inches in length and these would be able to grapple with birds of considerable size. We may conceive that the giant sundew would be able to hold out some special inducement for its intended victims to visit the leaves. Probably the bait would be in the form of some sweet-tasting secretion. On alighting the birds would probably not find the adhesive fluid which the leaves would produce more than slightly annoying. The movements which they would make in an endeavor to free themselves would be all sufficient to give the stimulus to the sensitive tentacles. These would rapidly close in on their prey and in a few moments escape would be out of the question. Finally the unfortunate birds would perish miserably, the bodies in their decay yielding to the plant the nitrogenous matter desired.

Possible enormous aristolochia flowers of the future which may lure even men

The Pinguiculas or butterworts are at the present time innocent looking plants rather attractive in appearance. These species as is well known find their home in boggy [illegible] where they spread their foliage on the surface of the ground in the form of a rosette. If the leaves of the butterwort are closely examined it will be seen that they are thickly covered with two sets of glands, one set of which is plainly visible to the naked eye. This visible set resembles a miniature mushroom while the other set is microscopic and is formed of eight cells grouped after the manner of a wart or a knob. It is the practice of these glands whenever they come into contact with any object to pour out copiously a mucilaginous fluid which acts much in the same way as bird lime. Acid secretion is also produced which aids the leaf in the digestion of the object—supposing that the capture should be an insect. In order to make assurance doubly sure the

CARNIVOROUS PLANTS OF THE FUTURE.

THE MOST ANCIENT OF HUMAN SKELETONS.

In February, 1909, the skull of one of our most ancient known ancestors was found at Chapelle aux Saints, in the French department of Corrèze. In September a nearly complete skeleton of approximately equal antiquity was exhumed at Ferrassie, in the department of Dordogne, by Dr Capitan and M Peyrony The strata which covered the skeleton were absolutely intact and the exhumation was performed so carefully that the bones were revealed in the precise positions in which they had been laid to rest, at least 20,000 years ago. This is the first instance in which so ancient a skeleton, found in such well-marked and indisputable geological surroundings, has been photographed at the moment of exhumation and before it had been disturbed

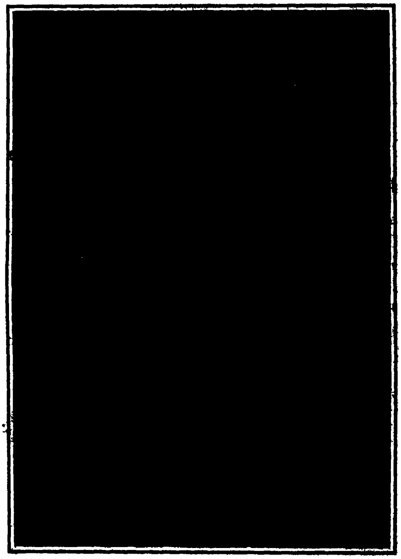
The region surrounding Ferrassie is peculiarly rich in prehistoric human remains and documents. Ten miles eastward are the famous caves of Eyzies, where the oldest known drawings on bone, ivory and horn were discovered nearly fifty years ago. In the neighboring cave of Cro Magnon Lartet and Christy, in 1858 discovered portions of five skeletons and two skulls which have recently been determined to belong to the Aurignacian race, a less ancient race than the Neanderthal to which the Corrèze skull and the Ferrassie skeleton appear to belong The same region includes the terraces of Monstier where chipped flint tools of peculiar character were found in 1863 The name monsterian has been given to the period of these tools, which succeeded the acheulean and its predecessor, the chellean, the most ancient division of the quaternary Relics of the cave dwellers have been found at various other points in the vicinity

This region has yielded, and will continue to yield, more human documents than any other part of France, for the following reasons During the monsterian period of the stone age the region was covered with prairies and forests and abounded in horses, cattle and deer, which, with the fish of the Vézère River and its tributaries, furnished a plentiful supply of food. Probably reindeer could also be found on the hills. Furthermore the river valleys are bordered by chalk cliffs and terraces, often overhanging, and honeycombed with caves, hollows and fissures, which formed excellent shelters. The deeper caves seem to have been reserved for funereal and religious uses, while savages dwelt in the shallower caves and, especially, beneath overhanging cliffs in front of which screens of boughs were constructed. A region which offered such advantages in regard to food and shelter must have been very popular in a primitive age

On the other hand it is certain that the general topography of the region has undergone little change since the monsterian period No geological convulsion has occurred The principal change is a deepening of the valley by about 30 feet, and this has further isolated the land at the base of the cliff, which was already well protected from inundation Men doubtless dwelt on the plains also in those remote times but all vestiges of them and their works have been destroyed or washed away by floods. Finally, all bodies buried in places distant from human habitations were quickly devoured by the hyenas which then abounded in France, and during the centuries that followed, the pick and the plowshare completed the destruction of the few bones that remained This is the explanation of the exceedingly rare occurrences of very ancient human bones in most regions and their comparative abundance in Dordogne.

The Ferrassie skeleton was discovered in the course of exploring a mass of debris about 100 feet long, sloping upward from the road to a low chalk cliff rising a few yards above it. The width of the mass varied from 30 to 60 feet and its height, at the cliff from 15 to 30 feet. The appearance of the superficial layer and the fissures of the cliff indicated the fall of an overhanging cliff, which should have formed an extensive shelter at a much earlier epoch As this view was confirmed by the discovery of chipped flints where the edge of the mass was cut by the road, explorations were undertaken several years ago but nothing of especial importance was unearthed until recently The excavation was begun by digging a broad trench from the road to the cliff in order to allow the mass to be removed in successive horizontal layers. Last September two bones were seen slightly projecting from the wall of the trench, near the bottom. On removing a little earth the bones were recognized as a human tibia and femur The earth over the bones was then removed, by horizontal layers, with extreme caution. When the greater part of the monsterian stratum had been removed, three flat stones, about eight inches square, covering the skull and parts of the arms, were discovered. The reddish brown sand which surrounded the skeleton contained many large splinters of bones of animals which showed marks of hammering. Very slowly and with infinite precaution the skeleton was laid bare without displacing a single bone. It lay on the back, with the trunk turned slightly to the left, and the legs sharply bent back under the thighs, which were half flexed on the pelvis. The knees were turned to the right. The left arm was extended beside the body, with the hand at the hip, while the right arm was bent, and the hand near the shoulder The head was turned to the left, with the mouth wide open.

The bones, though broken in places by the great weight of the earth above them, remained firm and in their normal positions. Only the bones of the right hand and foot had been displaced, and in part removed, probably by rodents or small carnivora.



THE MOST ANCIENT OF HUMAN SKELETONS.

The skeleton was photographed as it lay and the leg and arm bones were carefully removed. The pelvis was then covered with tinfoil and a large plaster cast was formed around it, so that it could be taken up without injury The thorax and the skull were treated in the same way Hence these parts can be mounted without the loss of a single fragment, as the earth in which they lay will surround them, inside the plaster casts, until the casts are opened in the preparing room This method is commonly employed by paleontologists, but this is its first application to human remains.

The age of the skeleton is indicated, with certainty and precision, by the regularity and very characteristic appearance of the successive strata of the mass in which it was found. (Age, in prehistoric chronology, refers, not to a definite number of years, but to a period of more or less hypothetical duration.) The quaternary geological period, in which man appeared on earth, began with the comparatively warm chellean age, which has left remains of the rhinoceros, hippopotamus, and elephant, and flint tools scarcely modified by man Then came the cold acheulean age, the age of the mammoth, marked by crudely chipped flints. The ensuing monsterian age, at first cold but subsequently mild, represents a higher civilization possessing a variety of [illegible] [illegible] [illegible] [illegible], [illegible] [illegible], [illegible] [illegible] very [illegible] of the [illegible]. [illegible] types were found [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] were found [illegible] [illegible]. [illegible] the skeleton is [illegible].

The stratum containing the skeleton was covered by two strata containing flint tools of the [illegible] age. The overhanging cliff then fell, and its debris subsequently became covered by a layer of earth and stones, five feet in depth, which has effectually protected the human relics beneath.

Dr Capitan believes that the skeleton is that of a corpse regularly prepared for sepulture, which may have been covered with earth, but was not buried in a grave. Protected by the vicinity of the living inhabitants of the shelter, the skeleton escaped the hyenas and was only nibbled by small animals. This unique skeleton, which is at least 20,000 years old, will probably be mounted and exhibited in the Museum of Natural History at Paris.

A New Substitute for Cotton.

The busy town of Chemnitz, the largest manufacturing center in the kingdom of Saxony and one of the largest factory towns of the German empire, has just witnessed the birth of a new invention which will doubtless cause considerable changes in the price of cotton and which, furthermore, will be of interest and importance to our readers in kapok-growing countries.

For some considerable time past the German textile world has been devoting unflagging attention to the discovery of fibrous plants which might in any way be rendered available as a substitute for cotton, and great interest has been given to the different more or less successful experiments made. Trials made with ramie and caravonica have been fairly successful, but have not met with that meed of success, nor attracted so much attention, which has fallen to the share of the experiments made with the fiber of the kapok tree (the so-called "silk-wool tree") which flourishes in America, Asia, and Africa. The fruit of this tree contains a seed which, like that of the cotton plant, is enveloped in soft silky hairs. These hairs, however, are so short that they have hitherto been useless to cotton spinners and have been used chiefly for upholstery and mattress-making purposes. Most kapok trees grow wild, and only recently have a few Europeans begun to cultivate them systematically in New Guinea and East Africa. Steps are also being taken to grow these trees properly in the German protectorates.

This new industry will be greatly favored by the process just discovered by a large German spinning mill, whereby it is now possible to render kapok fiber easily spinnable. So far, as an absolute matter of fact, the veritable fiber of the kapok tree has not been dealt with, but only the fibers of the Calotropis procera (a plant growing wild in East Africa); however, it is exactly the same as kapok fiber in character, appearance, and qualities. Hence, if the one can be spun, so can the other—a point on which not the slightest doubt is entertained. By means of a process evolved by Prof. Goldberg of Chemnitz, the brittle and fragile fiber of the kapok tree is treated in such a way as to render it easily spinnable, and yarn up to No. 12 English is now being spun from it. A sample, both of the raw material and of the yarn, may be seen at the offices. As will be seen, the yarn is of fine quality and of a very soft, silky, and tenacious character. The process in question does not necessitate the employment of any new machinery, but is based [illegible] [illegible] a novel and somewhat complicated system of preliminary preparation and spinning. What the actual process is cannot yet be divulged.

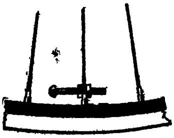
In the German African colonies fiber plants of all kinds are now being grown and, as Dr. [illegible] recently pointed out in a report to the [illegible] Kolonialwirtschaftliche Komité, the [illegible] [illegible] in German East Africa [illegible] [illegible] [illegible] [illegible] that in a few years that the [illegible] [illegible] will exceed 15,000 tons, and Germany will be able to meet her own requirements. [illegible] [illegible] [illegible] for the cultivation of [illegible] [illegible] [illegible] [illegible] being laid down there. [illegible]

(Concluded on page [illegible].)

IMPROVED NIPPLE GRIP.

BY [illegible]

When one wishes to replace a few broken spokes in a bicycle wheel, he often finds that he has no nipple grip, while a bicycle wrench proves to be too long to get in around the spokes. A good nipple grip can be made by putting two nuts on one bolt, as shown in the accompanying engraving.



IMPROVED NIPPLE GRIP.

◆

HOW TO WATER-PROOF CLOTH.

For rain coats or other water proof clothing, woolen goods having a close weave are the best. Use goods in which the face is smooth and firm, although cloth having a soft face answers fairly well, provided the weave is tight and close. To water-proof the cloth, lay it out on a large table face up. Then take a block of paraffine about six inches square and rub it all over the face of the cloth, bearing down hard This will leave a thin film of paraffine on the face of the cloth. Melt this film of paraffine into the goods, using a flat iron that is just warm. Too hot an iron will set the paraffine on fire and burn the goods. It is well to experiment with a small sample first, and learn how to do the water-proofing properly before starting in with a pattern of goods. To determine when the sample is properly water-proofed, hold it in a kind of bag, with the face in, and pour in some water If the water-proofing has been properly done the water will not wet the face of the cloth, but it will stay in globules and act as if it were on a greased board or hot stove.

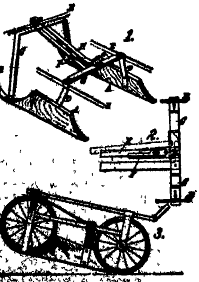
SLED RUNNER ATTACHMENT FOR GO-CARTS.

BY [illegible]

The writer made a pair of runners for his go-cart last winter which proved quite a success. They were made of 1 inch by ⅛-inch iron, and weighed altogether six pounds. The construction was such that they could be applied or removed in a few seconds. Referring to the accompanying illustration, it will be seen that two wooden side pieces *A* were provided, to which the runners *B* were fastened The wooden side pieces were cut out and grooved to receive the wheels, and the runners were curved up to fit against the front wheels. A [illegible] frame *C* of strap iron connected the runners at the forward end, while they were connected at the rear by a second [illegible] lower frame *D*. The frame of the go-cart is indicated by dotted lines at *E*. A pair of sliding members *G* were fitted onto the [illegible] *D*, and attached to a lever *F* in such manner that they could be extended [illegible] A strap *H* extending forward to the frame *C* was formed with a hook, so that when the lever *F* is moved to extend the members *G*, the strap *H* is retracted, causing the hook to fit over the front cross piece *E* of the go-cart frame. In applying the runners to the go-cart, it is merely necessary to raise the front wheels so as to clear the side pieces *A*, and then move the cart into position, after which the lever *F* is moved to lock the runners fast. One of the advantages of this system is that the runners at the rear are so short that when the cart is tilted backward the wheels rest on the ground, and in that position they can be wheeled over any bare spots.



SLED RUNNER ATTACHMENT FOR GO-CARTS.

A SNOW-BOUND SANTA CLAUS.

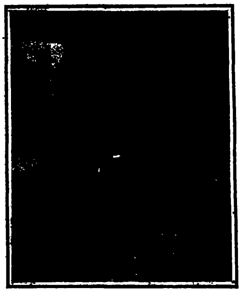
BY JOHN A. BERGSTROM

The accompanying illustrations show how a very pretty effect may be obtained in Christmas tree decoration. It has the appearance of a Christmas tree in a snow storm

Stretch a cord above and in front of the Christmas tree with one end fastened to a hook or a nail and the other end to the armature of an electric bell. Hang from this cord a number of fine threads to which at intervals small pieces of cotton are fastened The bell is connected up to a battery with a push button in the circuit. When this button is pushed causing the armature and cord to vibrate, the quivering bits of cotton look like falling snow The armature of the bell should be bent back a little so as not to strike the bell, which may be covered up with a wreath or other decoration

Fig 1 illustrates how the cotton may be attached to the threads.

A frame is first made a little longer than the curtain. This may be made out of any kind of rough lumber and nailed together At one end of the frame two rows of pins are put, about ⅛ inch apart The pins in each row should be about ⅛ inch apart At the other end of the frame is put another row of pins ⅛ inch apart.

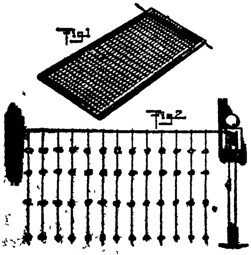


SANTA CLAUS IN A SNOW STORM.

Now wind the cord around the two rows of pins and fasten the ends, as shown Then fasten the end of a fine thread to the cord at the first pin Bring the thread down to the lower end of the frame and wind around two pins, then back again and fasten to the cord. Repeat until the required number of threads are obtained. Now take a fine brush, preferably a painter's striping brush, and apply glue to the threads, crossways, about two inches apart, the whole length of the curtain.

Cut some thin cotton batting into stripe about ⅛ inch wide, and place them across the threads where the glue has been applied, pressing them down onto the threads.

When dry cut the lower ends of the threads and pull each individual string away from the rest Just enough cotton will stick to each string After all the strings have been separated remove the cord at the upper end of the frame and the curtain is ready to be hung up Fig 2 shows a part of the curtain when finished with threads about 1 inch apart.



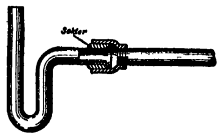
APPARATUS FOR PRODUCING THE SNOW STORM EFFECT.

◆

HOW TO MAKE LEAD PIPE INTO IRON PIPE WITHOUT A WIPED JOINT

BY HOWARD M. NICHOLS.

It takes a skilled plumber to make a lead pipe into an iron pipe, using a wiped joint but using the following method any mechanic can make a permanent joint which is equally as good as a wiped joint. The accompanying drawing shows a lead *S* made into a galvanized iron pipe The large end of a reducing coupling is placed over the end of the lead *S*, and the end is then flared out with a blunt piece of steel so that it will flare out and fit the coupling snugly, as shown The space between the lead pipe and the coupling is then filled with hot solder which is allowed to round out on the pipe and make a smooth joint. To complete the job the iron pipe is then screwed into the small end of the coupling



SIMPLE METHOD OF CONNECTING LEAD AND IRON PIPE

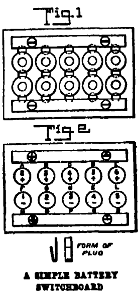
◆

A METHOD FOR CONNECTING BATTERIES IN COMBINATIONS.

BY CHAUNCEY W NIEMAN

The inventor who deals much with electricity is bound to find himself sooner or later greatly hampered in experiments with batteries by the necessity of frequent changing from parallel to series etc It is one of the little routine details which makes most of the worry in experimenting, for the connecting up of a dozen wires may often cause the loss of a happy inspiration" A convenient and easily made switch board is illustrated herewith and it will add its mite of comfort to the harassed inventor This board for six batteries allows all possible connections, and by adding more points can be adapted to any number of batteries

It is made as follows The board' is a one-inch piece of wood mounted if desired on feet. In this bore ten holes to receive an equal number of stove bolts, as per plan in Fig 1 The bolts should be provided with large washers and the holes so bored as to allow a distance of ¼ inch between the washers when in place Next two metal strips should be fastened by two stove bolts each, one strip on either side of the rows of bolts. The distance between the strips and the edges of the washers should be ⅛ inch also At the points indicated by the dotted circles bore ⅜ inch holes half way through the board Plugs should then be made, and consist of strips of sheet copper or brass ¼ inch broad, bent as shown Wires are then led from each pole of every battery and connected underneath the board to the bolts.



A SIMPLE BATTERY SWITCHBOARD

The wiring diagram is given in Fig 2 Batteries are numbered from 1 to 6, and the positive and negative of each battery are connected to the bolt so marked Current is taken off at the points *X* and *Y* An understanding of the key given below will enable anyone to make the combinations indicated with great speed and almost no trouble

Insert plugs at	to obtain
F, G, H, K, and *L*	all in series
C, F, G, K, L and *P*	2 parallel sets of 3 in [illegible]
B, D, F, H, L, N and *Q*	3 parallel sets of 2 in [illegible]
A, B, C, D, E, M, N, P, Q and *R*	all in parallel

POWER-DRIVEN SCOOTER.

BY FREDERICK E. LORD.

In the issue of January 9th 1909 there appeared plans for a scooter with description of how it should be built

The accompanying illustrations show how this scooter may be converted into a sort of automobile ice boat or auto scooter

The motor should be preferably an air-cooled one but as it may be difficult to get an outfit of ample power without high cost a water-cooled motor is shown in the plan as it is cheaper and there are a great variety to select from It will probably be necessary to experiment with the water system The plan contemplates a thin flat tank with a large cooling surface to act as a radiator If the weather is very cold this may be sufficient If not a simple radiator may be made by passing the water through thin copper tubing coiled in a spiral A seven horse power motor as shown weighing about one hundred and seventy five pounds and running at seven hundred revolutions, should give the scooter a speed of about thirty miles an hour on good smooth ice If a light weight air cooled motor of twenty horse-power is installed a speed of sixty miles an hour can easily be obtained

The propelling outfit may be installed in such a manner that it does not interfere with the use of the boat for sailing To do this it is only necessary to shift the gasoline tank forward and make the driving wheel case watertight the same as a centerboard trunk The steering runner could have a removable pin through the stock at the tiller head thus allowing the runner to be unshipped If the wind died out one could auto scoot home by simply putting in the rudder and starting up the motor Of course the extra weight and windage of the sails and rigging would retard the speed somewhat.

The first step in construction is to put in the trunk in which the driving wheel runs. First cut a slot in the bottom 12 inches long and 2 inches wide to allow the wheel to touch the ice The forward point of the slot is 5 feet 5 inches from the bow, if the boat is built accurately to the plans.

The old floor timber at station No. 7 will have to be cut amidships and a short one put in about two inches farther aft in order to allow sufficient space for the driving wheel

The two trunk posts are now put in These are of oak the forward one is 2½ inches wide and 3½ inches thick. It is jogged out as shown in the plan so that it rests on floor No 6 and supports the deck beam The post must be securely bolted to both floor and deck beam as a large part of the strain comes upon it The after post is 2½ inches by 2 inches securely fastened to floor No. 7

The sides of the trunk are of white pine ⅝ inch thick and put on two pieces to a side. The joint should come in line with the wheel bearing and be cut out around it to allow play for the driving wheel as it jumps over rough ice The lower boards should land on top of the bottom and be fastened to it with brass screws put in from underneath If the posts and boards are well fitted to the bottom and set in white lead the trunk should be fairly water-tight. A removable cap of ⅝ inch white pine allows the trunk to be inspected

The wheel yoke may next be shaped out. This comprises two pieces of oak 1¼ inches thick 2 feet 3½ inches long 4½ inches wide in the middle and 3 inches at the ends with a 1¾ x 3 inch cross piece to hold them together A 1⅝ inch hole is bored in them 1 foot 2 inches from the after end to take the flanged bearing of the driving shaft. Fig 2 shows the lay out of the yoke and trunk also the little ½ inch oak strips *AAA* which keep the yoke from chafing the sides of the trunk.

The driving wheel is of 1½-inch oak 15½ inches in diameter The rim is rounded over and fitted with twelve spikes. These can be made from 3⅜ inch iron lag screws Bore holes in the rim and screw them in Then cut their heads off with a hack saw and file them to a chisel point at an angle of about 45 degrees, as shown in the upper portion of Fig 4.

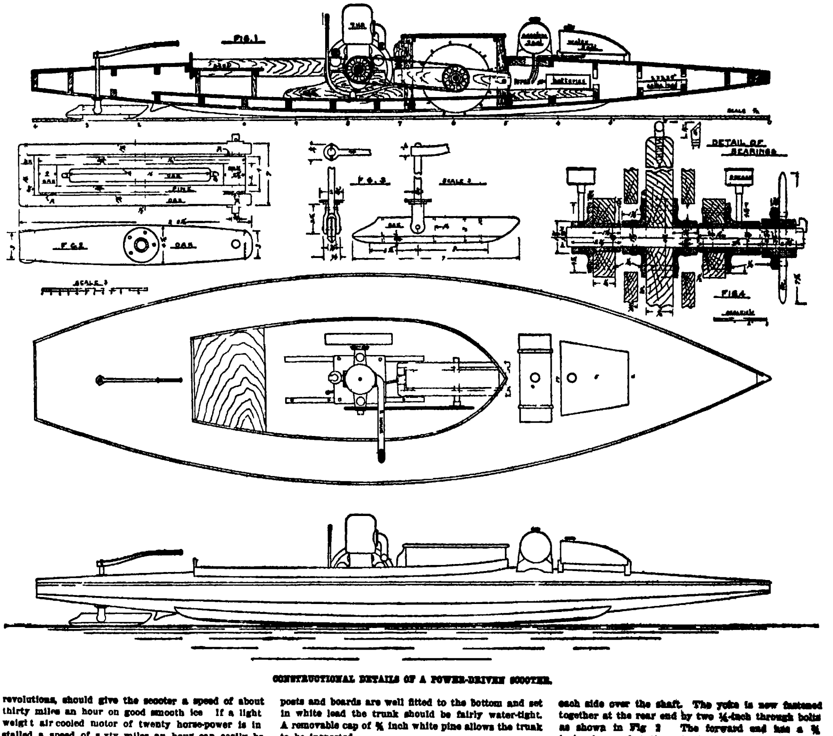
The small figure shows in detail the flanges and bearings for carrying the wheel and delivering the power The flanges should be bronze castings turned and fitted on a lathe. The cheapest way is to make one pattern large enough to enable all the flanges to be worked down from it. This would not be very expensive but the flanges must be well made or else trouble will surely ensue The driving shaft is of 1¼ steel 14 inches long A 7/16-inch driving sprocket about 7½ inches diameter is riveted to the flange and then keyed on to the shaft. As Fig 4 shows clearly the dimensions of flanges and rivets it is not necessary to describe them in detail. The driving wheel is pinned to the shaft with two 5/16-inch taper pins driven in tightly and riveted enough to prevent working out. A couple of grease cups are put in as shown.

To put the outfit together first pin the driving wheel on the shaft and lay it in the trunk, the two upper side boards being of course removed. Fasten the two bearing flanges on the yokes and then slip each side over the shaft. The yoke is now fastened together at the rear end by two ¼-inch through bolts as shown in Fig 2 The forward end has a ⅝ inch pin passing through the oak post tightly and having two washers and pins to keep the yoke together As the thrust of the motor is taken on this pin be careful to get it to fit the wood tightly A small through rivet forward of the pin will help prevent the wood from splitting. The sprocket may now be keyed on and grease cups fitted As the driving wheel will move up and down due to bumps in the ice it must be made flexible This is accomplished by means of the movable yoke and a spring fitted at the after end of the yoke to keep it pressed down hard on the ice and prevent the teeth from slipping.

An oak block is fastened securely to the trunk post and a 3/16 inch spring about 1½ inches in diameter and 4 inches long should be about right. Drive nails in a row around the spring to keep it in place

A means must be provided for raising the driving

(Concluded on page [illegible].)



CONSTRUCTIONAL DETAILS OF A POWER-DRIVEN SCOOTER.

RECENTLY PATENTED INVENTIONS.

Of Interest to Farmers.

GATE AND DOOR FASTENER.—F J S. [illegible], [illegible], Cal. In this patent the purpose of the inventor is to provide a novel, simple device for securing a door, gate, or the like in closed condition, the fastener being durable, and convenient to operate. The fastener is very desirable for use in the closure of an opening in a fence through which cattle are driven from one inclosure to another.

Household Utilities.

CANDELABRUM.—O. H. VAN GUELPEN, New York, N. Y. The candelabrum is so constructed that its arms can be turned around a central support, and the arms are so jointed and connected that their members can be placed in any position in relation to each other, and fastened in adjusted position, the adjustment being done with ease at the back or front of the device.

ANTISEPTIC TOOTH BRUSH HOLDER.—W D. JONES New York, N Y The holder is arranged to contain the brush in a tube filled with antiseptic vapors, to allow convenient removal of the brush for its legitimate use and replacing of the same in the tube and to supply the latter continually with vapors to maintain the brush when not in use in an antiseptic condition.

Machines and Mechanical Devices.

MACHINE FOR SHEARING METAL SHEETS.—G B. JOHNSON, 8 Victoria Street Westminster, London, England This machine facilitates and reduces manual labor incidental to the accurate shearing of sheets to a rectangular form, and is designed to overcome difficulties in such operations when performed by a single shearing cutter to which the edges of the sheet are successively presented, and more especially when it is required to simultaneously cut a number of roofing sheets in the "pack" as the latter is delivered from the rolling mill

NOTE.—Copies of any of these patents will be furnished by Munn & Co for ten cents each Please state the name of the patentee, title of the invention, and date of this paper

Legal Notices

PATENTS

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand-Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

FRICTION DISK DRILL
FOR LIGHT WORK.
Has These Great Advantages:
The speed can be instantly changed from 0 to 1600 without stopping or shifting belts. Power applied can be graduated to drive, with equal safety, the smallest or largest drills within its range—a wonderful economy in time and great saving in drill breakage. Send for Drill Catalogue.
W. F. & JNO. BARNES CO.,
Established 1872.
1999 Ruby Street, Rockford, Ill.

WORLD'S ELECTRICAL EXHIBITION JANUARY 15 TO 29 1910
Arrange to visit Chicago at this time and see everything new and wonderful in the field of Electrical Science, Invention and Industry. Manufacturers should reserve space now. ELECTRICAL TRADES EXPOSITION CO., Chicago, U. S. A.

WELL DRILLING MACHINES
Over 70 sizes and styles, for drilling either deep or shallow wells in any kind of soil or rock. Mounted on wheels or on sills. With engines or horse powers. Strong, simple and durable. Any mechanic can operate them easily. Send for catalog.
WILLIAMS BROS., Ithaca, N. Y.

H-C GAS ENGINE MAGNETOS
They are made right—work right and the cost is not high.
Send for Bulletin No. 1557

THE LIFE OF A SPLASH.

(*Continued from page 465.*)

attaining its greatest proportion, its walls begin to thicken, and gradually subside to form a mere ring of lobes on the surface, surrounding a central hollow.

Then comes a rebound, manifested in the rising of a central column which, after attaining its full height and subsiding, is followed by a secondary column ere the series of events which we term "the splash" is complete. Prof Worthington shows that the separation in the form of a drop of the top of the primary column ere its complete subsidence results in a series of events markedly different from that which ensues when no separation takes place. Moreover, the manifestation of outspreading ripples is affected by the condition of the surface, and in order to secure the most favorable conditions by cleaning the surface a continous slow stream of fresh water is maintained The contamination of the surface liquid, by the way, originates in lamp black brought down by each drop, for in order to prevent the drop from adhering to the watch glass in which it rests prior to its fall, it is found necessary carefully to smoke the glass in the flame of a candle But the atoms of lamp black which adhere to and are brought down with each drop serve to make clear some important points connected with the formation of the splash. They prove by their presence that the interior of the crater is lined by the original liquid which formed the drop, and thus afford useful information as to the nature of its flow When the primary column commences its ascent, the atoms of lamp black are carried upward at its summit, proving that the liquid of the original drop emerges at the head of the central column This is confirmed by allowing a drop of milk to fall into pure water, when the photograph shows that the upper part of the column contains nearly all of the milk. This fact may be easily verified by naked-eye observation, as indicated by Prof Worthington Let the reader drop from a spoon into a cup of tea or coffee, from a height of fifteen or sixteen inches, a single drop of milk. He will have no difficulty in observing that the column which emerges carries with it the white milk-drop at the top only slightly stained by the liquid into which it has fallen

Upon increasing the height of the fall of a drop to about 40 inches a new phenomenon is registered in the photographs. The crater rises to a greater height, but instead of subsiding in the form of a ring, its mouth closes to form a bubble on the surface of the liquid. If the height be not too great, the closing is either incomplete or at any rate only temporary, and the bubble reopens at the top to make way for the column which rises as before from the base, but is now much thicker and hardly so high as before With a very high fall, however the bubble becomes too firmly closed to reopen, and its summit is struck from within by the rising column, which becomes entangled in the liquid of the bubble when the latter bursts. Thanks, however, to the influence of surface tension, regularity of form is soon regained, so that the concluding events of a splash after a high fall agree in essentials with those which follow a low fall.

The facts elucidated by experiments with a sphere dropped from varying heights into liquid proved to be of great interest and importance. Prof. Worthington suggests that those who wish fully to grasp the significance of his photographs and deductions should experiment for themselves by dropping marbles from a height of about a foot into a deep bowl of water, the bottom of which should be protected from the possibility of breakage by a few folds of fine copper gauze A perfectly clean and highly polished marble so dropped will enter the water almost noiselessly with very little disturbance of the surface In a word, the splash is singularly insignificant. Photo-

A Highway of Communication

It goes by your door. Every home, every office, every factory, and every farm in the land is on that great highway or within reach of it. It is a highway of communication and every Bell Telephone is a gateway by which it can be reached.

Millions of messages travel over this highway every day In the great cities they follow one another like the bullets from a machine gun, and over the wide reaches of the country they fly with the speed of shooting stars

The Bell service carries the thoughts and wishes of the people from room to room, from house to house, from community to community, and from state to state.

This service adds to the efficiency of each citizen, and multiplies the power of the whole nation.

The Bell system brings eighty million men, women and children into one telephone commonwealth, so that they may know one another and live together in harmonious understanding.

A hundred thousand Bell employees are working all the time on this highway of communication Every year it is made longer and broader, and its numerous branches are more widely extended. Every year it is furnished with a larger number of telephone gateways and becomes the means of greater usefulness.

The Bell Long Distance Telephone will meet your new needs and serve your new purposes. It means — one policy, one system, universal service. Every Bell Telephone is the center of the System.

ON THE PRESS!
THE FOURTH DIMENSION
SIMPLY EXPLAINED
WITH AN INTRODUCTION BY
HENRY P. MANNING
Professor of Mathematics, Brown University
Price, $1.50 net. *260 pages illustrated*

A FRIEND of the Scientific American's donated a prize of $500.00 for the best simply-worded non-mathematical explanation of the Fourth Dimension. The prize was won by Lieut.-Col. G. D. Fitch, U. S. A. This essay, together with three others which were awarded honorable mention, was published in the columns of the Scientific American. As a result so much interest was aroused in the subject of the Fourth Dimension that it seemed advisable to collect, in permanent form, the more meritorious of the 245 essays which were sent in from all parts of the world.

The present work presents twenty points of view, all of them interesting and no two quite alike. Each essay is 2500 words in length. The reading of one essay does not involve the reading of the entire work, yet the entire book gives a comprehensive view of what the layman wishes to know about the Fourth Dimension. No abstract mathematics will be found in the volume. The essayists endeavor to explain the Fourth Dimension both by imagining the effect of transporting an ordinary third-dimensional human being into fourth-dimensional space and also by [illegible] third-dimensional man's possibilities in [illegible] dimensional space.

Professor Manning, the leading American authority on the subject of the Fourth Dimension, contributes an introduction in which he explains how the concept of the Fourth Dimension [illegible] mathematical prominence, and [illegible] the work that has been done in the field. He has also edited the essays and supplied explanatory footnotes where required.

ORDER FROM YOUR BOOKSELLER OR FROM

A $25,000.00 Magazine For 15 Cents

HAMPTON S represents the *new* type of magazine which first of all gives *news* and *information*. The time has gone by for magazines that simply give entertainment with articles mainly about travel astronomy literature, etc HAMPTON S publishes the things live men and women want to know about the *things they ought to know*, about their country their politics their financiers and their employers—the really big happenings in current history

To get this important material HAMPTON'S employs the most expert writers in the country and pays phenomenal sums of money for the work done. No newspaper publisher can afford to spend the immense amount of money and months of time which HAMPTON S lavishes upon its marvelous series of articles

The editorial and art material in each month s issue of HAMPTON S cost $25 000 entirely in addition to cost of paper printing binding etc One feature Peary s Own Story *to appear in only eight numbers cost over $50 000 alone.* This means that you get $25 000 worth of reading material for 15c or 1800 or more pages of the best reading matter in twelve numbers for $1 50

HAMPTON S during 1910 will be not only the best, but the greatest magazine in America—the most interesting magazine published. It is the *one* magazine you simply *must have.* Subscribe NOW

Peary's Own Story **The greatest magazine feature that has ever appeared. is one of twenty big features in**

JANUARY

HAMPTON'S

On Sale December 17th **15 Cents a Copy**

To be sure of getting January HAMPTON S you should order a copy from your newsdealer *at once.* A big edition is being printed but the demand will undoubtedly be tremendous *If you subscribe now* you will be sure to get this immensely interesting story complete also the great November and December numbers *Free.* Send HAMPTON S to your friends as Holiday Gifts It will give greater pleasure than anything else $1 50 could buy Gift Announcement cards beautifully printed in four colors and gold sent FREE, make the gift doubly attractive Send your orders immediately Prompt attention assured

HAMPTON S program for 1910 includes the biggest, most varied and important features ever before presented in any one magazine

ADMIRAL EVANS

will contribute articles dealing with the Panama Canal and other matters of national importance. No more valuable or popular magazine feature appeared during the past year than "Fighting Bob s navy articles in HAMPTON S His forthcoming series is of even wider interest His opinion on the Panama Canal published in January HAMPTON S is an especially valuable piece of analysis The Panama Canal will cost over $400,000,000 to build. It is the greatest business enterprise ever undertaken by the United States Government No one in the world is better qualified than Admiral Evans to say whether it is worth the price.

MARK TWAIN'S WORKS

at ONE-HALF former price

It has been Mark Twain's ambition to have his books in every American home and he has made a great personal sacrifice which brings about this remarkable situation—for the first time in the history of publishing copyrighted books are sold at the price of non copyrighted books

AUTHOR'S NATIONAL EDITION

25 Beautiful Volumes

Mark Twain is the youngest man of his day All his books are imbued with his spirit—they are new books, to *own* them is always to have new books, a fountain of youth They never age because humor kindliness and truth never grow old They are books for young people of all ages

Special Features of this Edition

Mark Twain himself has written a preface to the edition Brander Matthews has written the biographical criticism of Mark Twain and his work There are portraits of the author from photographs and paintings taken at periods when the different books were in process of writing This edition includes his later collected writings such as A Dog's Tale, Eve's Diary etc

There are beautiful pictures by such artists as Brown, Frost, Newell Beard Dillman Smedley Thulstrup Clinedinst Mora, Weldon Kemble, Gilbert, Du Mond, Merrill Opper

The binding is a beautiful dark-red vellum book cloth with blue title labels stamped in gold The books are printed on white antique wove paper especially made for this edition

The size of each volume is 5 x 7¾ inches

HARPER & BROTHERS

HARPER & BROTHERS

(Continued from page 474.)

graphic records show that the liquid, instead of being driven away from the surface in the form of a crater (as is the case when a drop or a rough sphere strikes the surface) now rises in a thin, closely fitting sheath which completely envelops the sphere even before its summit has reached the water level A comparatively insignificant column constitutes the subsequent splash Moreover and as a result of the rapidly closing sheath practically no air is carried into the water by the smooth sphere This point as well as many others of great importance was shown photographically by means of illumination behind a thin glass vessel with parallel sides—an arrangement which rendered it possible to photograph the splash both above and below the surface of the fluid Most of the photographs reproduced were taken in this way

So much for the splash caused by a smooth sphere If the reader will now fish out the marble with which he is conducting his simple experiments roughen its surface with sandpaper and again drop it from a height of a foot or so into the water he will find that a totally different splash results There is now a great noise of bubbles which may be seen rising through the liquid while a tall jet is seen to be tossed into the air Photographic records of the surface disturbance closely resemble those which have already been described caused by the fall of a drop A crater is formed and subsides and a graceful jet rises from its depths gathers volume from below and rises ultimately as a tall column whose height may be even greater than that from which the sphere fell Photographs of the descent of the sphere below the surface show us how this column originates The sphere as it descends drags with it the surface film of the liquid in the form of a gradually deepening pocket or bag which ultimately forms a long cylindrical hollow This eventually divides and the lower part is dragged down by the sphere to the bottom (no matter what the depth) whence it rises to the surface as a bubble Meanwhile the upper half of the cylinder rapidly fills up and this running together of the liquid is responsible for the great velocity of the upward spurting jet or column

On increasing the height of the fall of a rough sphere a higher crater which closes and forms a bubble is obtained just as when the height of fall of a liquid drop is increased With a fall of two feet this bubble is almost immediately destroyed by an upward jet But if the height of fall be increased to four or five feet no rebounding jet will be projected into the air notwithstanding the fact that much air is still carried down by the roughened sphere To the naked eye a curious seething' appearance at the surface is apparent and Prof Worthington admits that he was at first disposed to regard this as evidence of the entanglement of the jet with the bubble—an entanglement likely to produce confused motions which could not be profitably studied However the persistence with which the seething motion again and again returned when a stone was dropped or thrown into the river led him to suspect that something required investigation The remarkable change of procedure revealed in the series of photographs which was subsequently taken will be best described by a word for word quotation from Prof Worthington's writings 'The earlier figures show the very rapid rise of the crater and its closing as a bubble much before the entrapped column of air divides. Before the division takes place the liquid now flowing in from all sides closes over the upper end of the long air tube separates it from the air outside, and forms a downward jet which shoots down the middle of the air tube in pursuit of the sphere The first formation of this jet is not easy to observe because the view is obscured

Two Good Books for Steel Workers

Hardening, Tempering, Annealing and Forging of Steel

By JOSEPH V WOODWORTH

Size 6¼ x 9¼ inches 288 pages 201 illustrations Price $2 50 postpaid

THIS is a practical work treating clearly and concisely modern processes for the heating, annealing forging welding hardening and tempering of steel, making it a book of great value to toolmakers and metal-working mechanics in general. Special directions are given for the successful hardening and tempering of steel tools of all descriptions, including milling cutters, taps, thread dies, reamers hollow mills, punches and dies and various metal-working tools, shear blades, saws, fine cutlery and other implements of steel, both large and small The uses to which the leading brands of steel may be adapted are discussed, and their treatment for working under different conditions explained also special methods for the hardening and tempering of special brands. A chapter on case-hardening is also included.

The American Steel Worker

By E. R. MARKHAM

Size 6½ x 9 inches, 367 pages, 163 illustrations. Price $2 50 postpaid

THIS is a standard work on selecting, annealing hardening and tempering all grades of steel by an acknowledged authority. The author has had twenty-five years' practical experience in steel working, during which time he has collected much of the material for this book. Careful instructions are given for every detail of every tool Among the subjects treated are the selection of steel to meet various requirements, how to tell steel when you see it; [illegible] how to treat steel in the making of small tools, taps, reamers, drills, milling cutters, hardening and tempering dies [illegible] annealing, heating, [illegible] and, briefly, everything that a steel-worker would want to know is contained in this book

OUR SPECIAL OFFER: The price of these books is $2.50 each, but when the two volumes are ordered from us at one time we send them prepaid to any address in the world on receipt of $4.00.

MUNN & COMPANY, Inc. Publishers
361 Broadway, New York

([illegible])

by quick, unsteady and turbulent vertical motion resulting apparently from the streams that converge from all sides of the axis of the air tube at its upper end. . . . But (when) the turbulence has cleared away from the upper part, and from this stage onward the jet is well seen in all the figures, and it persists long after the segmentation of the air column has taken place. The reader must not suppose that this jet is a mere falling of the water under the action of gravity, for the rapidity with which it advances is far greater than could be accounted for in this way. The great initial momentum of the sphere causes it to continue in rapid motion after the bubble has closed, thus the sphere acts as a sort of piston, which by increasing the length of the air tube diminishes the pressure in it and so sucks in the bubble, which is driven down by the greater atmospheric pressure above. The converging horizontal inflow near the mouth of the air tube cannot, of course, produce the downward-directed jet without an equal and *opposite* generation of momentum upward; but this is now expended, not in producing a similar upward jet, but in balancing the excess of atmospheric pressure. The reaction, in fact, to the projection of the jet downward is the force which holds up and slowly raises the roof of the long air shaft." The rising of the roof is well shown in some of the accompanying photographs.

Thus, as Prof. Worthington points out, the formation of a downward jet is not, in a sense, a new phenomenon, but one which, having existed unnoticed before, is now rendered visible by reason of its being produced in air instead of water An increase in the height of fall to 22½ feet was found to produce but little change in the phenomena coincident to the resulting splash.

As an illustration of the possible application of knowledge gained from a study of splashes in an unexpected quarter, Prof Worthington draws attention to the fact that photographs of the splash of a projectile on striking the steel armor plate of a battleship bear a close resemblance to photographs of splashes caused by a sphere falling into liquid. There is the same slight upheaval of the neighboring surface, the same crater, with the same curled lip, leading to the inference that under the immense and suddenly applied pressure the steel has behaved like a liquid. The professor suggests that from a study of the motions set up in a liquid in an analogous case, it may be possible to deduce information about the distribution of internal stress, which may apply also to a solid, and thus lead to improvements in the construction of a plate that is intended to resist penetration.

In conclusion it should be said that the number printed below each photograph here reproduced gives the time in decimal parts of a second which has elapsed since the first instant of contact.

◆

CARNIVOROUS PLANTS OF THE FUTURE.

(*Continued from page 469.*)

edge of the leaf in certain species is seen to curl slowly inward Now we can imagine that in the very far-away future with which we are dealing the Pinguicula will develop leaves which will hardly be less than five or six feet in length. These lying along the surface of the ground will make a special appeal to grazing animals. Perhaps as with the sundew the allurement will be in the form of some pleasant-tasting secretion which is peculiarly attractive to sheep and goats. We can imagine how these animals at first coming across the plants would start to regale themselves at the prepared feast. The strong sticky substance would take a firm hold of the hairs surrounding the mouth parts of the creatures, and in their endeavor to free themselves the animals would become more entangled. Gradually, too, the sides

Handy Man's Workshop and Laboratory

Compiled and Edited by A. RUSSELL BOND

12mo. 467 Pages. 370 Illustrations.
Price $2.00 postpaid.

EVERY practical mechanic, whether amateur or professional has been confronted many times with unexpected situations calling for the exercise of considerable ingenuity The resourceful man who has met an issue of this sort successfully seldom, if ever, is averse to making public his methods of procedure. After all he has little to gain by keeping the matter to himself and, appreciating the advice of other practical men in the same line of work he is only too glad to contribute his own suggestions to the general fund of information About a year ago it was decided to open a department in the Scientific American devoted to the interests of the handy man There was an almost immediate response Hundreds of valuable suggestions poured in from every part of this country and from abroad as well Not only amateur mechanics, but professional men as well were eager to recount their experiences in emergencies and offer useful bits of information, ingenious ideas, wrinkles or "kinks," as they are called Aside from these, many valuable contributions came from men in other walks of life—resourceful men, who showed their aptness at doing things about the house, in the garden, on the farm The electrician and the man in the physics and chemical laboratory furnished another tributary to the flood of ideas. Automobiles, motor cycles, motor boats and the like frequently call for a display of ingenuity among a class of men who otherwise would never touch a tool These also contributed a large share of suggestions that poured in upon us It was apparent from the outset that the Handy Man's Workshop Department in the Scientific American would be utterly inadequate for so large a volume of material, but rather than reject any really useful ideas for lack of space we have collected the worthier suggestions, which we present in the present volume They have all been classified and arranged in eight chapters, under the following headings

I. Fitting up a Workshop, II, Shop Kinks, III Soldering of Metals IV, The Handy Man in the Factory, V The Handy Man's Experimental Laboratory VI, The Handy Man's Electrical Laboratory, VII The Handy Man About the House, VIII, The Handy Sportsman, IX, Model Toy Flying Machines. Index.

THEODORE ROOSEVELT'S
OWN STORY OF HIS
African Hunting Trip
NOW RUNNING IN
SCRIBNER'S MAGAZINE
is as popular as the man himself.

Every one wants to read it. The first article appeared in the October number and the entire first edition of that number was sold out in four days The Scribner presses are taxed to the utmost to supply the demand The articles are fascinating, full of adventure, and reflect the wonderful personality of Mr Roosevelt.

We will send Mr. Roosevelt's First Article in Booklet Form and Two Big Numbers FREE all to Scientific American Readers who Subscribe to Scribner's for the Year 1910

The subscription price of SCRIBNER'S MAGAZINE is $3.00 per year, but we will send to any reader of *Scientific American*, who subscribes for one year from January, 1910, *the November and December, 1909, numbers FREE;* also an attractive pamphlet containing *Mr. Roosevelt's first article in the October, 1909, number FREE.* We make this offer so that subscribers may have Mr Roosevelt's complete story

THIS offer is good for a short time only and should be accepted at once, before the great demand exhausts our edition. Write to-day, inclosing $3.00, and get Mr. Roosevelt's story from its beginning.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY - You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES

HAIR GROWS when our Vacuum Cap is used a few minutes daily. Sent on 60 days' free trial at our expense. No drugs or electricity. Stops falling hair. Cures dandruff. Postal brings illustrated booklet. Modern Vacuum Cap Co., 556 Barclay Block, Denver Colo.

Inquiry No. 8918.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

PATENTS FOR SALE.

FOR SALE.—Patent rights and business on the well-known Craven Folding Hair Brush, at an exceptionally low figure, if taken before Feb. 1st. A splendid opportunity. Address Perry-Austen Mfg. Co., Grasmere, Staten Island, New York.

Inquiry No. 8987. Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power meters.

FOR SALE.—Patent No. 1,077,871, an Electric Heater for various heating and warming purposes. Durable, convenient, economical and most useful. Price $1,000.00. Moise Landry, Hotel Carolyn, Turlock, California.

Inquiry No. 8990. For information regarding shoes not made of leather but similar to the same and are as durable.

FOR SALE.—U. S. Patent No. 811,929. A pump to inflate automobile tires by the use of the car's own power. Can be attached to any auto in a moment's time. Also Belgium, French and Canadian patent of above invention for sale. For full particulars and information address Frank Woodhead, Glen Riddle, Del. Co., Pa., Box 44.

Inquiry No. 8996.—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE.

FOR SALE.—Engine lathe, swings 9½ in., takes 25 in. between centers. Complete with full set change gears to cut all size threads, 8 to 40 in. Price only $45.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9014.—For manufacturers of machinery supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

HAVE several inventions for sale. B. Faldra & Co., professional inventors, 1 Palisade Av., W. Hoboken, N.J.

Inquiry No. 9018.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

WANTED.

FORMULA wanted for a Metal Polish, non inflammable preferred. G. H. Krumlviede, 25 Manhattan Av., N. Y.

Inquiry No. 9023.—Wanted, to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

Inquiry No. 9029.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9034.—For manufacturers of machinery that could reduce stumps to kindling wood.

Inquiry No. 9036.—Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

Inquiry No. 9040.—Wanted the address of Farney Safety Razor Co.

Inquiry No. 9044.—Wanted to buy outfits necessary for agate polishing.

Inquiry No. 9046.—Wanted machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

Inquiry No. 9047.—Wanted, the address of parties who install plants for making oxygen ozone gas.

Inquiry No. 9048.—Wanted, address of manufacturers of metal table slides for extension tables.

Inquiry No. 9049. Wanted, to buy rotary brushes suitable for a shoe shining machine.

Inquiry No. 9052.—Wanted to buy machinery etc., for a beer plant, that manufactures beer by means of glucose.

Inquiry No. 9053.—Wanted, address of firms who install plants to manufacture nitrogen.

Inquiry No. 9054. Wanted, address of manufacturers of articles made from mica.

Inquiry No. 9055. Wanted, address of parties interested in Log Cleaning Machines.

Inquiry No. 9056.—For manufacturers of window shades.

Inquiry No. 9057.—For manufacturers of glass and china balls, used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

How to Construct An Independent Interrupter

In SCIENTIFIC AMERICAN SUPPLEMENT 1615, A. Frederick Collins describes fully and clearly with the help of good drawings how an independent multiple interrupter may be constructed for a large induction coil.

This article should be read in connection with Mr. Collins' article in SCIENTIFIC AMERICAN SUPPLEMENT, 1605, "How to Construct a 100-Mile Wireless Telegraph Outfit."

Each Supplement costs 10 cents; 20 cents for the two. Order from your newsdealer or from

MUNN & CO., Inc., 361 Broadway, New York

(Continued from page [illegible])

of the huge leaves would close inward, and the fate of the victim would not long be delayed. A pitiable spectacle indeed to see these animals done to death by a plant, but the same process on a smaller scale is repeated thousands of times during the summer in any place where the Pinguiculas abound.

We can hardly think in this advance of vegetable life that the many species of pitcher plants which catch their prey more by allurement than by force, would be behindhand in the forward movement. Even at the present time many of these species develop processes which are several feet in length, as exemplified in the case of the Sarracenias and Darlingtonias. In one of the accompanying illustrations is pictured one of the colossal pitchers which in the course of ages may be evolved from the comparatively small Cephalotus—a native of Australia. There is no knowing what inducements these plants might not be able to hold out for the capturing of even man himself. Perhaps the tissue inside the pitcher would be peculiarly succulent, and we know that where there is anything worth having, there will always be found men daring enough to take the risk of getting it. Once inside the pitcher of the Cephalotus, escape would be possible only with a friendly assistant at hand. From the bottom of the pitcher three barriers would confront the prisoner anxious to get out. First of all there is a circular ridge projecting in such a way that it is most difficult to surmount. Secondly a stretch of wall thickly covered with processes resembling the teeth of a comb and all pointing downward. Last of all, on the involute rim round the mouth of the pitcher is arranged a fringe of decurved spines which resemble a row of formidable bayonets. Indeed, it would be a far more simple matter to get out of the average well than to make one's escape from a giant Cephalotus pitcher.

Although the matter does not involve death, the giant Aristolochia flower brings about the imprisonment of flies for quite a long time. The system is in connection with the cross-fertilization of the blossom. The insects are induced to enter the cavernous mouth of the great bloom by an odor strongly suggestive of carrion, which is peculiarly attractive to flies. Once inside, the flies are held captive by an ingenious arrangement whereby they are lost in the tortuous passages at the rear of the flower. After blundering around for some time the winged creatures are able to emerge again, not, however, before they have become well dusted with pollen for transmission to another bloom. It is possible that the Aristolochia of years to come will assume much larger proportions, and we may imagine that the flower will be able to hold out some allurement which will tempt large animals to enter its gloomy depths. It is more likely that escape from the colossal blossom would not be such a simple matter, and there might be a danger of a creature's coming unpleasantly near to starvation before seeing daylight again.

Far more dreadful than any of the plants described above would be the Venus fly trap of the future. This plant would be a vegetable terror. As is well known, the leaves of this plant are designed in the form of a trap. On the upper surface of each half of the leaf are three hairs. To touch any of them is to cause the organ to shut up, inclosing the object which has given rise to the irritation. The bordering of the leaf is formed of sharp fringed hairs which when the trap is closed prevent escape. At the most the leaves of the Dionæa are not more than an inch in length, but we may get a little idea of what this plant may be in years to come if we imagine the foliage to be large enough to grapple with a man. It is the habit of this plant to grow with its leaves half concealed beneath the sphagnum moss in which it thrives. The leaves of the giant man trap partly hidden by the undergrowth would form the

(Concluded on page [illegible])

PENNSYLVANIA R. R.

There are two trains that the world is watching. They are making records, and records on land and sea and in the air are watched these days. The

PENNSYLVANIA SPECIAL

is saving time and money to the business man by permitting him to snap down his desk at 4 o'clock and meet his associates in Chicago the next morning as they open theirs. In the mean time he may continue his business with a free stenographer at his elbow, or loaf with the conveniences of the club at hand.

The "Special" leaves Uptown New York at 3 55 P.M., Downtown by Ferry at 4.00 P.M., Downtown by Hudson & Manhattan Tube at 4 05 P.M., and arrives in Chicago next morning at 8 55. It kills time because it runs in the night.

"The 24-Hour St. Louis"

is giving the business man an entire afternoon for recreation at the club, or elsewhere. He may leave Uptown New York at 6 25 P M, Downtown at 6 30 (by Ferry), Downtown at 6.35 by Hudson & Manhattan Tube and reach St. Louis at 5 25 the next afternoon. He may enjoy a good night on an easy-running train and continue his work the next day with a stenographer at his beck and call, or he may do anything he can do at his club except play billiards.

He gets a whole day in New York.

These trains are not only time-savers, but nerve-resters.

They exhilarate and refresh. They may be banked on for time.

Instructive Scientific Papers

ON TIMELY TOPICS

Price 10 Cents each by mail

ARTIFICIAL STONE. By L. P. Ford. A paper of immense practical value to the architect and builder. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

THE SHRINKAGE AND WARPING OF TIMBER. By Harold Busbridge. An excellent presentation of modern views; fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

CONSTRUCTION OF AN INDICATING OR RECORDING TIN PLATE ANEROID BAROMETER. By N. Monroe Hopkins. Fully illustrated. SCIENTIFIC AMERICAN SUPPLEMENT 1500.

DIRECT-VISION SPECTROSCOPES. By T. H. Blakesley, M.A. An admirably written, instructive and copiously illustrated article. SCIENTIFIC AMERICAN SUPPLEMENT No. 1493.

HOME MADE DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS [illegible] and [illegible] contain excellent articles with full drawings.

PLATING DYNAMOS. SCIENTIFIC AMERICAN SUPPLEMENTS 720 and 793 describe their construction so clearly that any amateur can make them.

DYNAMO AND MOTOR COMBINED. Fully described and illustrated in SCIENTIFIC AMERICAN SUPPLEMENTS [illegible] and [illegible]. The machines can be run either as dynamos or motors.

ELECTRICAL MOTORS. Their Construction at Home. SCIENTIFIC AMERICAN SUPPLEMENTS 759, 761, 767, 641.

(Concluded from page 478.)

[illegible] plants that the world has ever seen. Any unfortunate man who should chance to stumble into one of these leaves would be speedily crushed to death by the steady pressure of the inclosing sides. One can imagine that a country in which the man trap abounded would be avoided as much as a district inhabited by man-eating savages.

The aquatic plants such as the bladderworts (Utricularia) would scarcely be behindhand in this forward movement among the carnivorous species. These plants capture small water creatures by means of little bladders which are attached to their stems. The entrance to these receptacles is guarded by a little door, which can be opened easily from the exterior but may not be pushed aside from the interior At the present time the bladders of the Utricularia are small, but there is no reason to suppose that they will always remain so. It is quite likely that they may increase in size so that they are able to grapple with good-sized fish and other water animals.

In these far-away days of which we have been speculating, plants will be divided into wild and tame sorts in the very real sense of the words. The botanical gardens of the time will be far more exciting than are the zoological collections of to-day It is fortunate that all natural changes come about with great slowness, and it may be that the condition of man himself will have changed considerably by the time he is called upon to face these aggressive plants. It is to be hoped that this may be so, otherwise the outlook for the human race is distinctly disquieting.

◆

A New Substitute for Cotton.

(Concluded from page 470.)

German East Africa, and the exports thence to Germany are steadily increasing. So far, little attention has been given to cocoanut fiber and the fiber of the many palms growing in the protectorates has been allowed to run to waste With a view to becoming independent of foreign countries for her supplies of this fiber, Germany is also going to see what can be done with the product of her own colonies. The whole aim of the German is to become "independent" and as far as possible, do without foreign goods and foreign labor Other instances could be given of this, were they not quite outside the scope of the present article.

◆

POWER-DRIVEN SCOOTER.

(Concluded from page 472.)

wheel clear of the ice when the engine is being started. This is accomplished by a lever of ⅝ x 1-inch iron placed and bent as shown in Fig. 1 When starting the motor the lever is pulled back and a small wedge of wood is slipped between it and the engine bed. After the motor has got going nicely it is slowed down and the lever gently relaxed, allowing the teeth to take a slight hold As the craft gathers headway increase the power and also the pressure on the spikes until the lever is slack and the motor running at its maximum power To stop, slow down and raise the wheel off the ice.

The construction of the rudder is simple. The stock is of ¾-inch iron 12 inches long. An 18-inch tiller of forged iron is pinned to the post with a ¼-inch pin. The stock is recessed and pinned to the iron yoke which carries the runner. This yoke is forged out of 1¼-inch iron and has a collar slipped over its shoulder to wear against another collar or flange fastened to the bottom to act as a bearing. A ¼-inch pin secures the yoke to the runner. The runner blade is of ¾-inch oak 1 foot 7 inches long and 2½ inches high.

For the shoe use a piece of [illegible] iron [illegible] inch deep and ¾ inch wide, cut to a V edge at an angle of 45 degrees on each side. The shoe should have a rocker of about [illegible] inch for the [illegible] inches; it is supposed to [illegible] on the ice. It should have 6 inches bearing forward of the rudder pin and 5½ aft The shoe is held to the runner by three ⅜ through bolts riveted and smoothed off A guard is placed under the boat to prevent the runner from catching in obstructions

The engine can now be installed For a foundation use two 1¼ inch oak stringers running along four frames and shaped and spaced as per requirements of engine used. The stringers should be through bolted from the outside of planking to top of the bed and drawn up tight and solid

Now set the motor in its bed and fasten down with ½-inch lag screws 3 inches long The exhaust is piped over the side and the water and gasoline tanks are situated on the forward deck They each hold 3 gallons, and should be made out of 18-ounce copper The piping is led down through the mast hole along the floor to the motor It should be of copper tubing, ¾ inch for the gasoline and 1¼ inch for the water

The batteries and coil are placed just under the tanks. Six dry cells are sufficient. In order to have the scooter trim with one person on the seat it will be necessary to put about 60 pounds of lead up forward as shown As the keels of these boats are rockered, attention must be paid to this or else the pressure on the rudder will be too great or it will be lifted clear

A ½ inch heavy motor cycle roller chain should stand the strain with care but as to the diameter of sprockets experiments would have to determine this as it would vary for every type of motor With the driving wheel turning up 700 revolutions per minute the scooter would be going about 33 miles per hour If the motor could turn up to that or over it would be better to let it run up and gear it down.

With a motor of six or seven horsepower and turning 700 to 800 per minute I would use for a starter an 8-inch sprocket on the driver and a 7 inch one on the engine.

A printed copy of the specification and drawing of any patent in the foregoing list or any patent in print issued since 1863 will be furnished from this office for 10 cents, provided the name and number of the patent desired and the date be given. Address Munn & Co Inc 361 Broadway New York

Canadian patents may now be obtained by the inventors for any of the inventions named in the foregoing list For terms and further particulars address Munn & Co., Inc. 361 Broadway New York.

Big Money In Drilling

Our customers all over the Country are making from $25 to $75 profit a day with the Cyclone Drill. No business offers such big returns for the money invested.

Contractors, prospectors, well drillers, find the Cyclone Drill more economical, faster and easier to operate than any other.

We make Hollow Rod, Cable and Core Drills, to meet every need.

We also make combination machines that will handle any or all of the systems equally well, a machine that will enable you to cover the entire field of drilling

Cyclone Drill

Our Diamondite and Steel Shot Core Drills cut faster and at fraction of the cost of the old diamond drills. We sell Cyclone Drills on an easy payment plan Some of our customers have made more than the price of the machine within one month. Our new traction Gasoline machine—only one made—is of particular value where fuel and water are scarce. Send for our free books on Drilling, and let us know in what branch of the work you are interested.

THE AUTOMOBILE NUMBER of the SCIENTIFIC AMERICAN

Issue January 15, 1910

THIS year bigger and even better than it ever was. It has been our purpose in publishing this annual review to give the automobile owner and the prospective purchaser truly helpful information, and to that end the number will contain the following articles:

1 The Automobile and the Farmer.

2 How to Overhaul Your Car

3 The Automobile Fire Engine

All the latest automobile pumping engines, chemical cars, hook and ladder trucks, and hose carts are described.

4 The Automobile and the Road.

The automobile has presented to the road engineer new problems for solution. He must render his roads impervious to water and practically proof against the destructive effect of tires. The United States Government through the Office of Public Road Inquiry is now studying this subject. The article written by Mr Page, Director of the Office of Public Roads, describes what has been done.

5. Anti "Joy Ride" Devices.

This article is a complete description of devices which have been invented for the purpose of preventing chauffeurs from taking out their owners' machines.

6 The Modern Electric Automobile.

7. Making Your Own Repairs.

8 The Cars of 1910

9. Automobile Identification Chart.

Sometimes you have wondered what make of car was that which skimmed past your admiring eyes. The 1910 Automobile Number will enable you to identify any car by its radiator and engine bonnet. About thirty-five automobiles are thus illustrated for identification in a sketchy, artistic way.

10. The Inexpensive Car.

Any man with a good salary can now afford to own some kind of an automobile. How the machines are constructed and what may be expected of them is lucidly set forth.

11. The Wonderful Rise of the Automobile Industry.

12 Automobile Novelties.

A Little Book About Fort Smith

Send to-day for it and find out about the opportunities offered in the most rapidly growing city between St Louis and Dallas

Did you see our advertisement "WE WANT FACTORIES"?

We want more now

Fort Smith Arkansas offers to capital seeking investment in factories and to individuals or corporations having manufacturing plants and looking for new locations the best proposition possible to-day in the United States

Fort Smith is situated in the center of almost fabulously undeveloped wealth of semi-anthracite coal the largest gas field in the United States vast deposits of building stone, and in the close neighborhood of approximately twenty billion feet of commercial hard and soft wood timber

Fort Smith has forty thousand population—nine railways—and is the natural and logical center for the manufacturing and wholesale market for the Southwest

Fort Smith has splendid homes fine schools and churches beautiful parks and public buildings and every street in the city is being paved It presents magnificent opportunities for both labor and capital Jobbing trade now $40 000 000 annually

We want factories of every kind and character, and will make every reasonable concession to parties desiring to locate here

For further information address the COMMERCIAL LEAGUE, Fort Smith, Arkansas

Remoh Gems

Look like a diamond—wears like a diamond—brilliancy guaranteed forever—stands filing like a diamond—stands heat like a diamond—has no paste, foil or artificial backing. 1/20th the cost of diamonds. Set only in solid gold mountings. A marvelously reconstructed gem not an imitation. Sent on approval. Write for our catalog, it's free. No canvassers wanted. *If not satisfactory money refunded*

A WARNING.

It is quite conceivable that the great loss of property and the equally serious loss of prestige occasioned by the fall of the Quebec Bridge have been already fully compensated by the valuable lessons learned from that disaster It was worth the loss of a Quebec Bridge to learn that tests of the strength of a small model can no longer be taken as a basis in estimating the strength of a structure which is an exact reproduction of that model on much larger scale. That was the principal illuminating fact brought out by the commission which made an exhaustive examination of the wrecked bridge. Furthermore, it was proved that when the members of a framed structure are themselves made up of a large number of assembled pieces, as in the case of built-up chords, posts, girders, etc, the results obtained on the smaller models are particularly unreliable in determining the strength of the full-size members.

If it be necessary to proceed with caution in the case of a structure in which the assembled parts consist of the same kind of material possessing similar elasticity and breaking strength, there is a call for even greater caution when the materials of construction are not homogeneous, and the bond between them is of a more or less doubtful character This last condition exists in the case of reinforced concrete construction, and especially when it is used in the building of truss bridges and similar framed structures.

We are therefore in thorough accord with our esteemed contemporary Engineering News when it draws attention editorially to the construction of a reinforced concrete truss, the strength of which was determined, or attempted to be determined, by the testing of a model of one-tenth the linear dimensions and one-hundredth the cross-sectional dimensions of the finished bridge Our readers will remember that in the various failures which we have recorded of reinforced concrete, the breakdown has most frequently occurred at the points of junction of one member to another, such, for instance, as the connection between a floor beam and a vertical post It is admittedly difficult to design these connections in such a way as to render it possible to determine their strength with the same certainty that obtains in designing such a connection in an all-steel structure, and a concrete truss bridge, because of the multiplicity of the joints and the complicated character of the stresses which occur, must be particularly liable to this uncertainty

We have no wish to throw any general doubt upon reinforced concrete construction as such, but we do believe that now that a determined effort is being made to apply the system to the more difficult problems of bridge work our engineers should proceed with the greatest caution, and advance only upon well-proved data The call for testing machines capable of trying out to absolute destruction the largest size members is particularly urgent when these members are built up of such widely different materials as steel and concrete, the strength of the bond between which is greatly dependent upon careful work during erection.

ELECTRIFICATION OF A CHICAGO RAILWAY TERMINAL.

At a recent meeting of the stockholders of the Illinois Central Railway, the proposal to electrify the terminal lines of that company in the city of Chicago was rejected. The city now proposes to force the hand of the railway company by means of local ordinances. The railway company objects to the change on the ground. First, that there is a heavy interchange of traffic with other railways that use the Illinois Central terminal, and secondly, that the main line and suburban passenger and freight tracks are all included in the terminal system. Therefore, it would be difficult and enormously expensive to equip the entire system for electric traction, while serious difficulties and dangers would result from the operation of the yard and the switching service by electric traction.

These objections have a familiar sound in the ears of residents of New York city, who have not forgotten the agitation which preceded the wonderfully successful installation of electric traction at the terminal of the New York Central Railroad Company in this city. They are also mindful of the fact that, long before the electric service was in full operation, the Chief Engineer of the railroad announced that the benefits derived by the railroad company itself, to say nothing of its patrons, from the new service exceeded even the most sanguine expectations. Not only was the city freed from the nuisance of smoke and noise, but the railroad company itself was able to handle its trains more expeditiously, and to reduce the number of train movements enormously Although no definite figures have been given out as to the decrease in the cost of operation, it is generally understood that the reduction has been very considerable

We confess to considerable surprise that so enlightened a journal as Engineering News should side with the Illinois Central Railway in its present obstructionist policy, which it does by stating that it is "unreasonable to make the objection of the people of Chicago to the noise and dirt from the engines a basis for saddling the railways with the enormous cost of converting the entire terminal system to electric traction"

It seems to us a simple matter of equity that the holders of a valuable franchise should bear the expense of any changes that will render their operations under that franchise as free as possible from inconvenience and nuisance to the city that gave it The smoke and noise arising from the operation of the Illinois Central tracks by steam, constitute a most serious disfigurement and drawback to the Chicago water front, and the great improvement which resulted from the electrification of the terminal of the New York Central Railroad will be even more marked in the long stretch of water front which is now so greatly marred by existing conditions at Chicago.

REPORT OF THE NAVAL BUREAU OF ORDNANCE.

We learn from the report of Rear Admiral Mason, Chief of the Naval Bureau of Ordnance, that the tests of the new 12-inch 50-caliber gun showed it to be fully equal to any gun of that caliber thus far proposed for any navy In the proving ground tests it developed an initial velocity of 3,030 feet per second and a muzzle energy of 52,500 tons. This is the gun that will be mounted on our two largest "Dreadnoughts," the "Arkansas" and "Wyoming," which will carry twelve guns of this pattern. More powerful than this, however, will be the new 14-inch type gun, which will pass through its tests before the end of the present year It is designed to fire a 1,400-pound projectile with a velocity of 2,600 feet per second and a muzzle energy of 65,600 tons.

It is gratifying to learn that our present nitrocellulose powder has been developed to a point which leaves little room for improvement. Moreover, a new pattern of projectile is now being built, carrying the long pointed head that has been found to give such good results in small arms, which has shown a considerable increase in range, flatness of trajectory, danger space, striking velocity, and penetration at the longer ranges. Our older guns have been modernized, and this work has included the relining and strengthening of the 12-inch guns of our battleships of a date prior to, and including, the "Virginia" class.

The Bureau is much gratified at the remarkable results which have been obtained in target practice with equipment which was designed many years before the present principles and demands of target practice had been developed; and a new system of sighting mechanism has been worked out, and is being applied to all turret guns. Our latest ships are being fitted with complete refrigerating plants for the cooling of the magazines, and the magazines of the older ships are to be similarly fitted as opportunity offers. Changes have been made in the rotation band of projectiles, which will considerably prolong the accuracy life of the projectiles after the gun has been so much worn that its accuracy with the older bands would have been much impaired.

THE ARMY ORDNANCE REPORT.

In his Annual Report, Gen. Crozier, Chief of Ordnance, U. S. A., speaking of the occasional failures of heavy guns, states that the trouble arises not from a defect in the design of the guns, but from concealed defects in the forgings or the development of erosion or heat cracks. The danger arises from [illegible] as soon as these [illegible] noticed. [illegible] ber and over, [illegible] will be double tubes, so that, should the inner [illegible] the damage will not extend to the outer [illegible] enveloping jacket and hoops. This will [illegible] restoration at small cost of guns [illegible] and will facilitate the rehabilitation of guns whose accuracy has been lost through erosion [illegible] bore.

The six 6-inch and four 14-inch guns authorized by Congress at its last session will be of the [illegible] type and will have [illegible] and in the 14-inch guns the caliber length [illegible] calibers, as in the guns now under construction [illegible] calibers. Within the next few months the Department hopes to test the new [illegible]-caliber 14-inch wire-wound gun and one of the new 12-inch wire-wound mortars.

The construction of hand grenades for the army marks the reintroduction of an ancient form of weapon. They were used with good effect, we believe, in the Russo-Japanese war. The grenade can be thrown by hand a distance of about 150 feet from a standing position. Lieut.-Col. Babbitt has designed a rifle-shrapnel grenade to be fired from the musket carried by the infantry. Troops will be furnished with both the hand and rifle-shrapnel grenades in a reasonable quantity whenever there is a call for them.

Another item of interest gleaned from the report is that Gen Crozier is of the opinion that the government can now manufacture cheaper than it can buy; that is, if everything is taken into account except the manufacturers' profit. As an instance of this, he quotes the fact that the 3-inch field gun, which under contract costs $2,020.80, can be manufactured at the arsenals for $1,376.90, and that the 12-inch disappearing carriages, which cost under contract $1,[illegible], cost only $605.35 when built at the arsenals.

THE ORIGIN OF EUROPEAN PEOPLES.

In a recently published work on the origin of European peoples, Sergy recognizes eight races of men, only three of which have left remains in caverns. These races are *Homo Europæus*, *H. Eurafricus*, *H. Eurasicus*. The first race is extinct. It was characterized by a very low forehead and an enormous protrusion of the glabellum and the superciliary arches, forming a sort of visor. Remains of this race have been found at Taubach, Krapina, Neanderthal, Spy, Schipka, La Naulette, and Malarnaud. Sergy assigns the middle of the Pliocene as the period of this race.

The second race is still in existence. It has a visorless skull, dolichocephalic or mesocephalic. It came from the north of Africa and has left remains in the loess of Egisheim, Galley Hill (England) and Predmost (Moravia), and in the caves of [illegible], Chancelade, and Baoussé-Roussé. Sergy attributes to this race the palæolithic civilization of the later Quaternary in the south of France, and finds in that civilization analogies with the Mycenæan or prehistoric Egyptian civilization, apparently later than the Quaternary but in reality contemporaneous with it in the development of the arts. There is no apparent reason why this race should not have penetrated into the southwest of France.

The synchronism of two ages, however, is very difficult to prove, because the palæontological criterion of the Quaternary is not uniform throughout Europe, owing to differences in climate. For example, no trace of *Elephas primigenius*, *Rhinoceros tichorhinus*, or *Cervus tarandus* has yet been found in Italy.

Homo Eurafricus persisted into the neolithic age at Cro-Magnon, Baumes-Chaudes, [illegible] Toward the end of the [illegible] (*Homo* [illegible]) [illegible] Asia and left remains [illegible] in the still [illegible]

[illegible]

ENGINEERING.

The "Vanguard," the new British "Dreadnought," recently completed an eight-hour trial at the remarkable speed of 22.4 knots, a full knot in excess of the Admiralty's stipulation.

In the endeavor to apply a slow-speed turbine economically to cargo steamers the Parsons Company purchased the cargo steamer "Vespasian," and, after running her with a careful record of steam and coal consumption, they have taken out the engine and put in turbine machinery of the same power The vessel is now being run under exactly similar conditions as to load and speed, and, before long, valuable particulars of the relative efficiency of the two types of engine will be available.

A number of motor cars for the suburban service of the New Haven Railroad are now being completed at the Westinghouse shops. They are 70 feet long, weigh 56 tons, and seat 72 persons. The cars are equipped with motors of 300 horse-power, and each is guaranteed to haul two 50-ton trailers at a normal acceleration of 0 7 mile per hour per second They are designed to operate on both the 11,000-volt alternating current of the New Haven, and the 600-volt direct current of the New York Central Railroad

The Public Service Commission for New York city has published designs for the elevated portions of the new subways, which have been approved by the Municipal Arts Commission. They embody, among other things, a scheme for deadening the noise of the trains, which consists of a concrete floor, 11 to 15 inches in thickness, upon which the wooden ties will be laid. The æsthetic appearance of the structures will be improved by the use of curved steel brackets connecting the columns with the longitudinal and transverse girders.

According to a report from Washington, the officers of our latest and fastest torpedo boats of the "Flusser" and "Reid" type, which have made a speed of over thirty-three knots on trial, are to be furnished with special headgear equipped with a form of automobile goggles to protect them against the fierce rush of wind and spray Thirty-three knots is equal to about thirty-eight miles an hour, and at this speed, especially when steaming against a strong wind, some form of protection to the eyes becomes a positive necessity

The New Haven Railroad is constructing a mile of experimental overhead trolley line beyond the Stamford terminus of its present electrical road. The new system is designed to lessen the weight and cost, and eliminate certain undesirable features, of the existing style of construction from Woodlawn to Stamford Apart from the reduced cost, the new construction will have the great advantage that the trolley wire only will be alive and carried upon the customary insulators, breakages of which have been frequent. The main cables will be strung directly from the supporting columns.

In a series of experiments to determine whether concrete could be conveyed in the plastic condition from the place of mixing to the point where it was to be deposited, Messrs. Bussell and Larkin recently made some experiments which seem to determine the feasibility of this plan The experimental plant, as described in Engineering News, consisted of a hopper tank maintained under compressed air, in which the concrete was placed, and from which a pipe led to the point of deposit. Half a cubic yard of broken stone concrete was deposited at the end of 400 feet of 4-inch pipe in less than 5 seconds.

The second attempt to raise the United States cruiser "Yankee" to the surface of Buzzard's Bay failed at the very moment when it appeared to be successful. The method adopted, as explained and illustrated in our issue of November 27th, was to exclude the water from certain compartments by forcing in air under pressure, and thereby give the vessel sufficient buoyancy to bring her to the surface. On December 2nd the vessel was raised until the top of the deckhouse aft was three feet above the water At this stage a certain portion of the hull or deck gave way, allowing the air to escape, and the vessel settled to the bottom. Further details of the mishap will be given in a later issue.

In an exhaustive analysis of the various types of aeroplane, a writer in Engineering gives the following particulars: The Wright biplane for each horse-power weighs 41.6 pounds and spreads 21.6 square feet of surface. For the Farman biplane the respective quantities are 34.2 pounds and 8.3 square feet; and for the Curtiss biplane, 18.3 pounds and 9 square feet. Among the monoplanes the Antoinette, per horse-power, weighs 20.8 pounds and spreads 7.2 square feet of surface; the Bleriot weighs 19.2 pounds per horse-power and spreads 6 square feet; while Santos Dumont's little machine, the "Demoiselle," weighs only 8 pounds per horse-power, or one-fifth as much, and spreads 2.3 square feet of surface per horse-power, or less than one-fifth as much as the Wright machine.

ELECTRICITY

An International Congress of Radiology and Electricity will be held at Brussels next year on September 6th, 7th, and 8th. The subjects to be taken up for discussion are the methods of measuring radioactivity, theories of electricity and radiations, and the effect of radiation on living organisms

The American Electro-Chemical Society has appointed a committee to devise a method of rating and testing dry cells. The present methods have long been considered unsatisfactory, but have continued in force because of the difficulty of obtaining a rating which would be applicable for the various uses of the cell.

A new safety lamp for miners has been invented, comprising a battery and a metal filament lamp which are completely incased. The circuit of the lamp is kept closed by means of a spring-pressed rod bearing against a light ring on the glass casing of the lamp Should the glass be broken, the ring would be sure to break or be displaced, opening the circuit of the lamp so that there would be no danger of igniting the gases with the incandescent filament

The city of Chicago is discussing the possibility of utilizing the water power obtainable from the Drainage Canal to extend the street lighting system A large part of the city is illuminated with gas and gasoline lamps but by making use of the power from the Drainage Canal these lights could be replaced with electric arcs. There are 18,000 arc lamps now in use, and if the gas and gasoline lamps are done away with, 29,000 arcs will be required

During one of the automobile endurance tests between San Antonio and Dallas, Texas, one of the entrants, who is president of a telephone company, carried telephone apparatus with him, and by using a long fishing pole could tap the telephone lines along the route without leaving his car By this means he was able to keep in touch with points in advance of the run and arrange for relief in case of accident or for hotel accommodations

The city of Austin, Texas, used to have a large lake, formed by a huge dam built across the Colorado River This dam was 1,275 foot long and 67 feet high above bedrock A plant placed just below the dam converted the water power into electricity, which was used for lighting the city and operating the street railways, as well as for a number of industrial plants In 1900 the dam and power plant were washed away by a flood, and the city was too crippled to replace them A movement is on foot now to rebuild this dam, making it of reinforced concrete The power obtainable will probably attract many manufacturing industries, which would undoubtedly contribute materially to the development and growth of the city

Now that Christmas is here, and amateurs are lighting their trees with electricity, it is well to call attention to the warning issued by the Chicago Board of Underwriters to the general public, and especially to merchants who have holiday window displays Ordinary Christmas decorations are highly inflammable, and it is even more important to take every precaution with the wiring than if the wiring were to be permanently used in the store or house Chicago merchants have been warned to have special watchmen keep guard at their windows during the danger season.

A new form of mercury interrupter has recently been invented in which there are no reciprocating parts, but the interruptions are produced by a ripple formed in a stream of mercury The mercury is contained in a revolving vessel within which a contact piece is fixed The mercury is thrown by centrifugal force to the inner periphery of the vessel. At one point the stream of mercury is obliged to pass over a deflector, producing a ripple or wave, and the contact piece dips into the mercury stream at this point as it revolves with the vessel The frequency of the interruptions may be varied by having the deflector revolve slowly in the same direction as the vessel is revolving, or in the opposite direction, or having it remain stationary

An inventor has recently devised a form of explorer for locating conductors when searching for faults in a high-tension underground cable. It depends for its operation upon the fact that the three conductors of the ordinary cable are spirally wound with a pitch or "lay" of 20 inches. By connecting two of the conductors at the power station, signals which are sent out through the conductors form magnetic lines of force that lie at right angles to those produced by ground currents in the sheath of the cable Consequently, the magnetic circuit of the instrument is unaffected by these currents. By using a double telephone receiver in connection with the instrument signaling currents sent over the line produce very intense sound when the explorer is on the sheath and the sound is quite noticeable, even when the explorer is placed on the tile duct outside.

SCIENCE.

Dr. Ludwig Mond, the distinguished chemist, died on December 11th in his London residence at the age of sixty years. Dr Mond was well known as the inventor of many valuable commercial processes, among them the process for the manufacture of ammonia and soda and producer gas.

In view of recent discussion concerning the possibility of adopting an international set of symbols for the principal electrical engineering quantities, Prof A. E. Kennelly has made a statistical examination of recent textbooks in various countries. The results of his examination are published in the Electrical World It seems that there are twenty-one quantities in the list and fifteen subsidiary fundamental quantities.

In his "Reminiscences of an Astronomer," the late Prof Simon Newcomb took occasion to pay a tribute to the brilliant work of Dr George W Hill of West Nyack, N Y That tribute was paid we suspect not only because Prof Newcomb admired Dr Hill's remarkable mathematical attainments but also because he wished to drive home to the public some conception of the value of his service as one of the Naval Observatory staff No doubt Prof Newcomb would have rejoiced with every American scientific man in the awarding of the Copley Medal to Dr George W Hill, the highest distinction conferred by the Royal Society

An earthquake was recently felt at a mineral spring in Austria. Soon after the shock the water of the spring was found to deposit a brown sediment and to evolve more carbon dioxide than usual The water soon became clear but the abnormal evolution of gas continued for several hours Mineral springs at great distances from the center of disturbance have often been observed to be affected by earthquakes Prof Suess explains the phenomenon as follows Agitation of a supersaturated gas solution causes a rapid evolution of gas, as may be proved by shaking a bottle of soda water The gas is evolved still more copiously when the solution is thrown into molecular vibration After an earthquake the rocks surrounding even distant springs are thrown into vibration, which is transmitted to the water causing rapid evolution of gas, expansion of the mixture of gas and water and expulsion of solid particles

The Radium Institute of America was formed at a meeting in the building of the New York Yacht Club recently The purpose is to study radium, discover any radioferous deposits in the United States, and buy quantities of it in Europe for clinical use in the United States. It is the idea of the founders to establish a clinic in connection with some New York hospital, where radium treatment will be administered free to those needing it The Institute will take steps to protect the public from the false claims of patent medicine manufacturers that certain of their remedies contain radium, and will set a standard that those desiring to deal in radium commercially will have to live up to Dr Charles F Chandler was elected president, Dr Robert Abbe, vice-president Prof William Hallock, secretary, Prof George B Betram, assistant secretary, and Dr Hugo Lieber treasurer

Prof. A. Mallock has made a careful study of the utilization of the energy stored in springs for the production of mechanical work with the object of showing in what way the work stored in stretched India rubber may be most fully utilized so as to supply power at a constant rate It seems that the most convenient form in which the India rubber can be used is that of a long strip or band wound on a drum or reel under tension, and in order to convert the potential energy into mechanical work Prof Mallock shows the conversion cannot be effected continuously but must proceed in cycles and that the condition of efficiency is that each portion of the elastic band whose contraction is being utilized must be unwound from the drum without change of tension and that the part so unwound must then be isolated by clamping or otherwise and allowed to contract without contact with other bodies except at the clamped ends

The third annual convention of the American Society of Agricultural Engineers will be held at the Iowa State College Ames Iowa on December 28th and 29th The society was formed at Madison Wis in 1908 by a few men, most of whom were then engaged in teaching agricultural engineering in the universities throughout the country The importance of the work to be accomplished by such an organization was soon realized by prominent manufacturers and others interested in this field both commercially and professionally, the result being that during the last two years the membership of the society was increased fully four hundred per cent A word explaining the term "agricultural engineering may be of interest to many who have not become fully acquainted with the work. Within the scope of the term falls a study of farm machinery farm buildings farm conveniences and irrigation and drainage In short it deals with the mechanical side of farm life involving teaching, investigation, and manufacturing activities

A NEW THEORY OF THE SCREW PROPELLER.

Prof. Oswald Flamm of the Technische Hochschule at Charlottenburg, the principal engineering school of Germany, very recently completed a remarkable investigation of the action of a ship's screw propeller As a lecturer on naval architecture and engineering, he admitted that the theory of the marine screw had worked out very indifferently in practice. His investigation, which involved formidable complications, was reduced to a highly mathematical form, but on concluding his practical experiments, Flamm was nearly ready to deny that the theory had any real value. Propellers elaborately calculated on that theory were found, in practice, to require so much "cutting and trying" that calculation was simply wasted. The entire theory is now regarded by him as a mere dry abstraction It gives no clear idea of the precise physical motion that a screw imparts to water

Flamm finds that the most obvious features of a ship's screw were entirely overlooked by its originators, yet these very features indicate the real reasons for a propeller's action One of these was the seething mass of water immediately behind a steamer's stern, and another, that familiar condition of any cast off propeller, that when they have lost their usefulness they have a peculiar shape The edges of the blades are always rough and irregular through erosion. Why are only the ends in that condition while the hub remains unimpaired? Prof Flamm's experiments not only explain this paradox but also dispose of two very common notions, that a screw at the highest speed of its revolution, loses propelling effect through 'cavitation" (a vacuum formed in the water behind the blades) and that the propelling effect may be increased by inclosing the propeller in a tube to prevent water that is being acted upon, from escaping at the sides.

VELOCITY OF PROPELLER, 8 METERS PER SECOND.

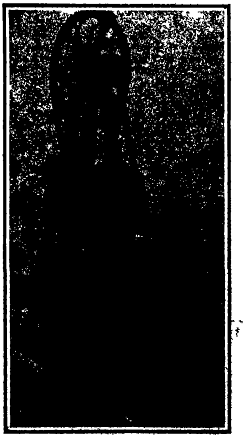
Flamm's method of investigation meets the problem so clearly and fits the requirements so perfectly that it seems odd he should have been the first to try it. Much of our useful knowledge about screw propellers has been obtained at great expense by fitting propellers of various designs to a ship and in this way, measuring their efficiency Flamm constructed a testing apparatus which reproduced similar conditions on a small scale at less cost, and at the same time permitted more complete and accurate observation and measurement.

A screw was observed while it was propelling. The minutest features of the process, the water itself, were photographed by means of extremely sensitive plates that gave perfect pictures at exposures of only 1/1000 part of a second. It had been intended to make the stream lines visible by adding an opaque powdery substance to the water, as used successfully in photographing the stream lines around moving bodies This was not necessary, enough air was mixed with the water by the propeller to make the screw's movement plainly visible These pictures were stereoscopic and kinematographic views. The apparatus was very simple, a long glass tank filled with water, over which ran a small car along a railing, to the car was attached an electrically-driven screw propeller immersed in the water There was no track resistance to the car, to which was fastened a cord running over a pulley at one end of the tank This cord was attached to a cup for holding weights. The cup's range of fall was as long as the tank, therefore the resistance of the car to propulsion was measured with exactness. From one side of the tank two electric arc lights of 24 000 combined candle-power, sent their rays through the water on the level of the propeller, to the photographic lens on the opposite side The tank was 32 feet and 9 inches long and 2 feet and 7 inches wide and deep, the diameter of the propeller was less than 4 inches. Fourteen different patterns were tested, including all the standard types. Accurate measurements were obtained of the number of the propeller's revolutions and of its push but the amount of energy it consumed could not be determined with the same accuracy in this simple apparatus nor was it possible to ascertain the maximum push any certain propeller was capable of giving except when the car was held stationary Even so, many conclusions may be drawn. It is evident that a propeller's efficiency depends on the processes in the water, and that these processes obey definite laws. Flamm discovered a sucking action to be the real basis of the efficiency of all screw propellers. In naval practice, a ship's propeller is quite near the meeting line of water and air, this fact gives the sucking action a peculiar "by-effect" that is so incidental and variable, it has escaped much critical attention. As a result, all former theorising was futile.

All the Flamm pictures show a positive dent in the water-level, immediately above the screw's periphery—the water is being sucked down to the screw's center with such force that it cannot flow in quickly enough from the sides to fill up the vortex. Flamm states that this dent exists even around a freight steamer's propeller when it is so far out of the water that the top blade projects above the surface. The water's quick turbulency on the slopes of this dent engulfs air, which is taken down to the blades, this peculiar adhesion and attraction between air and water produces foam. Consequently, the screw does not work on water alone but on water mixed with more or less air Thus is explained the paradox, how an implement placed as far below the surface as a ship's screw, whips the water into a frothing mass. Another fact, hitherto unsuspected, is presented by these experiments What has been called the propeller's "slip," that difference between its pitch speed and the velocity with which it drives the ship, is variable for the same energy and size and shape of the screw. It depends on the volume of air that is sucked in, this in turn depends on various conditions.

PROPELLER SUCKING IN AIR FROM SURFACE.

Flamm found that the phenomenon attending any sudden loss of efficiency of a ship's propeller when it is driven above a certain number of revolutions a minute, was not one of "cavitation," as heretofore assumed. "Cavitation" has been explained as the hollowing out of water by the screw, meaning that the blades when passing too rapidly through the water, leave an instantaneous vacuum in their wake, thus losing their "grip" on the water, as a whip-lash leaves a vacuum in the air On the contrary, it has been demonstrated that in all these cases of so-called "cavitation," the suction from the water's surface had become so strong that an immense volume of air rushed in from above, with the suddenness of an explosion. The water is instantly whipped into foam around the propeller, the blades lose all hold and the screw races away furiously as it does when lifted entirely out of the water when the ship pitches violently In Flamm's experiment, with the propeller working at very high speed, the car was dragged back by the weight in the cup.



A MACHINE FOR FIRING BLASTS SIMULTANEOUSLY.

There was an obvious remedy either under the experimental conditions or in water more or less smooth. When the car was fitted with a board that covered the water-level on top of the revolving screw, it permitted running the propeller even at higher speed; no "cavitation" occurred because the air was excluded. The efficiency of a ship's propeller may also be increased by a stern having a long overhang immediately below the surface. [illegible] any air screws [illegible] that would [illegible] half-cylinder of water [illegible] would be wasted. Everything therefore [illegible] the screw as far below the surface as possible. This seems to explain the efficiency that is obtained in fast motor boats by inclining the propeller's axis. Even a layer of water no deeper than the screw's diameter was not a very efficient shield against the entrainment of air. It was still more curious that when the revolving speed at which the board excluded "cavitation" was only slightly exceeded, "air tubes" were formed in the water. These traveled from the edge of the board to the propeller, again destroying efficiency. It was necessary to have the shielding board of ample size.

Observations of a worm-shaped air-space behind the hub of the experimental screws were not productive of much surprise. This was a neutral space without suction or pressure, as indicated by introducing a small tube. Air blown through that tube considerably increased the waterless space below the surface. Nevertheless, Flamm found that true "cavitation" exists, but that, quite contrary to established notions, it marks the very climax of a screw's efficiency. As this efficiency depends to its greatest extent on suction, it becomes evident that a screw is most efficient at the moment there is enough suction to actually create a vacuum. "Cavitation" is wasteful in that from the instant it begins, any increasing of the number of revolutions per minute does not increase the propeller's efficiency at the same rate that it costs power It cannot increase a suction that is already at its maximum. These tests of real "cavitation" were conducted under a large protecting board. It was also found that starting a screw very suddenly increased the air-suction to a marked extent.

VELOCITY OF PROPELLER, 3.7 METERS PER SECOND.

Prof. Flamm obtained a great number of excellent photographs. The air sucked in not only illustrates the stream lines next to the propeller but also reveals the wake of the blades for considerable distance behind the propeller On examining these photographs, the reason propellers corrode at the edges of the blades, becomes very clear, especially upon considering that each little dent when first created by the erosion becomes a nest for air bubbles. Suction is strongest at the edges of the blades. Prof Flamm also gave great attention to skin friction of the water He advises running a propeller rapidly because the friction that forms an important part of its resistance to revolving, increases at a lower power of the speed than its push, and because "cavitation" may be obtained with a small screw He found wide blades wasteful of power He designed a very efficient screw with increasing pitch and narrow blades. These trials are to be resumed on a larger scale.

A MACHINE FOR SIMULTANEOUSLY FIRING MANY BLASTS.

BY FRANK C. PERKINS.

The electric machine for exploding blasts pictured in the accompanying illustration is said to effect a reduction of one-third in the amount of explosive used, on account of the simultaneous firing of the charges.

All the charges must be exploded at the same instant, this being far more effective than a number of intermittent explosions, separated even by only a fraction of a second.

The electric firing machine illustrated consists of a small dynamo of 12 volts pressure mounted on the base of the machine, and driven with a crank by means of sprocket wheels and chains, the best results being obtained from a dynamo 25 per cent over-compounded. By the use of the hand-operated machine, it is stated that one hundred casts have been fired at one time, all of the charges exploding precisely at the same instant.

An electro-magnetic switch, mounted on a marble slab on the front of the machine, accomplishes this desired end, and the current from the dynamo first passing around the coil of the electro-magnet, which has an iron core. The magnetic strength of the iron core increases as the current around the coil becomes stronger while the dynamo is being speeded up. When the electric generator is working at full speed and the current is strong enough to explode all the fuses at once, a vertical armature is pulled over, and its [illegible] is sufficiently energized. A catch on the vertical shaft noted at the right of the coil in the illustration is thereby released, and a spring pulls the [illegible] with a jerk. A switch beneath the coil is [illegible]

(Concluded on page [illegible].)

A POLLEN-GATHERING PATENT DEDICATED TO THE PUBLIC.

Mr. [illegible] Moulié of Jacksonville, Fla., has invented a pollen-gathering device, patents for which he has dedicated to the public, for the general good. Furthermore, he will place the device at the disposal of scientific men who are interested in the gathering of pollen. The apparatus is suitable for universities and colleges, and such institutions where botany is taught.

The importance of the invention may perhaps be gaged if we consider the previous methods of gathering pollen. With the first of his machines Mr. Moulié, under the most favorable circumstances, gathered one and a half ounces of pure pollen of the ragweed (*Ambrosia Artemisiaefolia*) in three days, and this with three charges of twigs, one for each day. It was the opinion of the late Prof. A. A. Curtiss, a prominent botanist, formerly connected with the Smithsonian Institution, that to collect that amount of pollen it would have taken one hundred persons thirty-six hours.

Mr. Moulié's device consists of a vessel provided with means for holding the slips or twigs bearing the blossoms from which the pollen is to be collected. The vessel is filled with water, so as to keep the twigs fresh and ripen the blossoms. The blossoms overhang the edge of the vessel, so that the pollen falls upon a paper sheet spread closely around the bottom of the vessel, which bottom is narrower than the top of the vessel, so that the paper is free to be removed without touching the vessel. The vessel or tank is made of sheet metal. Over the top of the tank is a sheet metal plate supported over two longitudinal and two transverse rods, the edges of the plate being bent around the rods. This cover plate is smaller in area than the top of the tank, so that a narrow channel or opening is formed around the entire perimeter of the plate. The rods project across this opening, their ends being bent over the rim of the tank. Into the openings around the plate the twigs and branches are inserted, their lower limbs being immersed in water. The branches are tilted, so that their upper ends project beyond the sides of the tank. To keep them in this position, and to prevent them from sliding too far into the tank, the cover is cut at the center to form a pair of flaps, which are bent outward and engage the stems. As previously stated, the tank is surrounded by sheets of paper, on which the pollen falls as the blossom ripens. The ripening is brought about by the gradual rise of temperature in the room where the operation takes place. When desired, the water in the tank may be drawn off without disturbing the branches, through a tube connected with a stopcock near the bottom of the tank. Fresh water can be poured through an opening in the cover plate. The device renders it possible to collect the pollen of flowers in unlimited quantity in its full state of fertilising power, a thing impossible to be sure of by the ordinary process, hitherto the only method available. The ease with which much pollen can be collected at practically no cost renders it possible to obtain a sufficient quantity for accurate and exhaustive analysis, and to add to our knowledge of that wonderful mystery of nature, the breeding of plants. Moreover, an antitoxin for diseases such as hay fever could probably be prepared from the pollen of the ragweed. If the device served this purpose alone, it would reflect considerable credit upon its inventor.

To obtain pollen from the ragweed, Mr. Moulié selected a room having a single window exposed to the east, two windows exposed to the south, and one window exposed to the west. The apparatus was charged with twigs bearing ragweed flowers which were not quite open. The charged apparatus was placed upon a table extending from one end of the room to the other, with a space of two feet between the apparatus and the walls. The vessel was filled with clean water poured in through the opening at the top, care being taken not to spill any of the water on the flowers. The paper was then spread around the apparatus, so as to cover a sufficient space from the bottom of the apparatus to about six or eight inches beyond the perpendicular line of the top of the twigs, so that the pollen could not drop outside of the paper. The paper employed was a thick Manila brand. After the apparatus was installed, all the windows and adjacent doors were closed, and a Rochester kerosene lamp having a burner one inch in diameter was placed on the floor. To avoid the danger of fire, the lamp was placed in a large tin can. After the lamp had been lit, the apparatus was left to itself, and the door of the room locked until the next morning.

MOULIÉ POLLEN GATHERER.

The twigs selected must be used as quickly as possible after they are gathered. Moreover, they must be gathered in the morning before the sun is too high but not before they are free from moisture (dew or rain). This brings the work of gathering to about noontime. After the room is opened, care must be taken in opening the doors, so as not to create a draft which might blow the pollen off the sheets upon which it has dropped during the half day and night. The door must be closed immediately for the same reason. The temperature at that time ought to be between 85 and 88 deg. Fah. In order to gather the pollen Mr. Moulié took one sheet loaded with it and placed it on a table in an adjacent room, closing the connecting door between the rooms as well as the windows and other openings. The pollen was collected by means of a feather and dropped into wide-mouthed two-ounce jars similar to those in which vaseline is sold. The jars were filled to about one-half inch from the bottom. The collected pollen contains a certain amount of moisture which must be evaporated for safe keeping. To effect this, Mr. Moulié placed the jar or jars behind the windows in the room where the apparatus was installed, and arranged them so that they touched the windows. The rays of the sun streaming through the window pane and the glass jar caused evaporation to take place in about thirty minutes. Then after shaking gently until there were no more lumps the jars were brought into the next room and left there for one hour before they were corked. The corks selected were of the best quality and wrapped with a fine paraffine paper, so as to effect a tight closure. Small quantities of pollen can be poured in a single jar to the height of the neck. Very few readers of this journal realize what an ounce of pollen means. Perhaps some conception of the task may be had, if one imagines the collecting of an ounce of dust from the wings of butterflies.

PHOTOGRAPHING A STAR SPECTRUM

BY PROF. S. A. MITCHELL, COLUMBIA UNIVERSITY

If one should go to the Sandy Hook lightship off the entrance to New York Bay and at night should see the lights of a steamer headed for the harbor, it would be practically impossible merely by looking at these lights to learn how fast the steamer was approaching. A rough guess might be made by watching the lights grow gradually brighter but it would be the roughest sort of an approximation. But the astronomer with his telescope, observing the distant stars millions on millions and millions of miles away, can tell to an absolute certainty just how fast a particular star is moving toward us or away from us, giving the motion accurately to the fraction of a mile per second. Nor is this result obtained by watching the increase or decrease in the star's light, due to its approach or recession, for the stars are so far distant that no change in their brightness would be observed in a thousand years from their change of distance alone. The measurement of a star's motion in the line of sight is one of the new fields for the astronomer, and many and valuable are the scientific results accruing from this line of work.

The writer was at the Yerkes *Observatory last summer*, taking part in the campaign for measuring the radial velocities of all the brighter stars that can be seen from northern latitudes and assisting in photographing the spectra of stars with the 40-inch telescope and its attached spectrograph. And what a magnificent instrument this greatest refractor in the world is! To work with this great telescope causes a feeling akin to awe in realizing that puny man, on this infinitesimal speck in the universe called earth, by the aid of such an instrument is able to fathom the depths of space and reveal the secrets of stars millions and millions of miles away. Truly there is no science which can show the matchless power of the human mind quite so well as does the old science of astronomy, the parent of all the sciences. A view of the largest refractor in the world shows also the high degree to which engineering skill has advanced in recent years, again attesting to the close union between pure and applied science.

The observatory presented to the University of Chicago by Charles T. Yerkes, is situated seventy-five miles from Chicago on the shores

PHOTOGRAPHING A STAR SPECTRUM.

A Proposed Revival of Spinal Anæsthetization.

A distinguished European surgeon is now visiting New York. The gentleman is Prof. Jonnesco, of the University of Bucharest, and his mission is to demonstrate the value of surgical anæsthesia without loss of consciousness. The procedure which he is understood to advocate is that of injecting into the spinal canal a solution of stovaine and strychnine. The demonstrations which he has thus far given in New York have been highly satisfactory, and it is felt that he has made great advances in the technique of spinal anæsthetization. Nevertheless, there is really nothing new in his method

The synthetic compound known as stovaine has for several years been recognized as an efficient local anæsthetic, and moreover, it has been used to some extent within the rhachidian canal There is, too, no novelty about Prof Jonnesco's procedure even in the addition of strychnine to the solution employed, for Dr J Leonard Corning, of New York, who first employed spinal anæsthetization, used strychnine with cocaine experimentally more than twenty years ago If the high point at which the injection is given is regarded as a novelty, let him who so regards it remember that, as early as in 1899 Dudley Tait had made injections between the sixth and seventh cervical vertebræ Prof Jonnesco's main achievement seems to us to lie in the fact of his nice adjustment of doses to individual cases

It must not be forgotten that the danger incident to spinal anæsthetization is not the sole cause of the comparative desuetude into which the practice has fallen, there are in many cases grave objections to the very existence of anæsthesia without loss of consciousness though there are a few surgeons who still push the use of local anæsthetics beyond what seem to us to be the bounds of reason. Local anæsthesia in its proper sphere is unquestionably a boon, for general anæsthetization has not yet been freed of all drawbacks. Nevertheless, it appears to us that, for all but minor operations, the embarrassment which may arise in consequence of a patient's consciousness must often outweigh those drawbacks

Prof Jonnesco is properly meeting with a fair hearing, but we must deprecate the newspaper notoriety with which his mission has thus far been attended, though it has been mild in comparison with what has sometimes accompanied the exploitation of similar undertakings. Its tendency is chiefly harmful by reason of its leading the public to expect the impossible and to insist upon imposing its own inferences upon surgeons who undertake major operations It is manifest that such a state of things is not only undesirable, but positively detrimental to the satisfactory practice of surgery —New York Medical Journal.

Fraud in Electric Lamps.

English technical journals have been warning purchasers of incandescent electric lamps against swindlers who install lamps which purport to contain metallic filaments but which soon prove to be very short lived carbon filament lamps. The lamps, when first installed, give a brilliant light and appear to be very economical, as tested with the agent's ammeter but the bulbs soon become blackened, the luminosity diminishes and in a short time the lamps break—often breaking the insurance also They are simply ordinary carbon filament lamps, overloaded. When an incandescent lamp is subjected to a voltage higher than that for which it is designed it gives a very brilliant white light, and, on the other hand, the light becomes weak and reddish if too low a voltage is employed The swindle is operated by putting, for example 150-volt lamps on a 200-volt circuit. The overload of 50 volts accounts both for the initial brilliancy and for the short life of the lamps. Bulbs of ground glass are employed, so that the purchaser cannot see the alleged metallic filaments.

THE PHASES OF VENUS.

BY PROF FREDERICK R. HONEY, TRINITY COLLEGE.

The present time offers an excellent opportunity for observations of Venus, which is now evening star, and may be seen for some time after sunset. The planet is daily approaching the earth, and increasing in brilliancy

With the exception of Mercury, no other planet presents as great a variety of phases, but Mercury's diameter is not much more than three-eighths that of Venus, and on account of Mercury's greater distance from the earth at inferior conjunction, the apparent diameter is not as variable as that of the more brilliant planet. While Mercury is rarely seen, owing to his proximity to the sun, Venus as evening star is visible after sunset, for several months, and again for several months as morning star, she is visible before sunrise, no other planet approaching as near the earth.

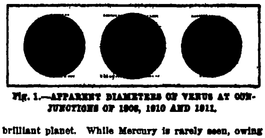

Fig. 1.—APPARENT DIAMETERS OF VENUS AT CONJUNCTIONS OF 1908, 1910 AND 1911.

The mean distance between the earth and Venus at inferior conjunction is about twenty-six million miles, with a variation mainly dependent upon the position of the earth in its orbit. The eccentricity of the orbit of Venus is less than that of any other planet, and is barely visible in the plot. It is less than one-third of e, the linear eccentricity of the earth's orbit, which is a little over one and a half million miles.

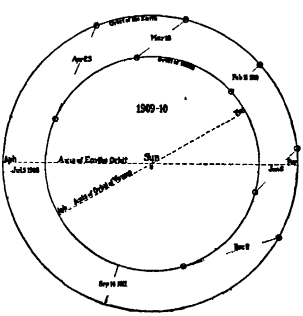

Fig 2—THE ORBITS OF VENUS AND THE EARTH

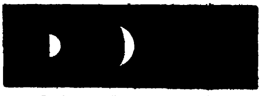
The last inferior conjunction occurred on July 5th, 1908, when the earth was near aphelion, and the distance between the planets was very nearly twenty-seven million miles. The next inferior conjunction will occur on February 11th, 1910, when the distance will be reduced to twenty-five and one-third million miles. The interval between inferior conjunctions is about one year and seven months. That of 1911 will occur on September 14th, when the distance between the earth and Venus will be nearly twenty-six and a third million miles. These distances correspond with those shown in the plot of the orbits, and the difference between them is apparent even in a drawing which is made to a scale small enough to bring it within the limits of this page. The effect of this variation of distance in changing the apparent diameter of Venus is shown in Fig. 1, which represents the planet magnified as it would appear projected on the sun's disk at the time of a transit. Its apparent diameter is inversely proportional to its distance from the earth. At the date of the approaching conjunction (February 11th, 1910) the planet will be very much nearer the earth than at either the preceding or succeeding conjunctions.



Dec. 2.
Jan. 6.
Feb. 11.

Fig 3.—PHASES OF THE PLANET VENUS.

Fig. 3 shows Venus at the date of the greatest elongation from the Sun (December 2nd) when the half-moon phase is presented, and at the date of greatest brilliancy (January 6th, 1910) which is the crescent phase. In order to show the rapidity with which the apparent diameter increases as Venus approaches the earth during the months of December and January, the outline of the planet is faintly traced as it would appear, were it possible to see it on February 11th.

Fig. 3 inverted gives the phases which will be repeated after conjunction, when Venus will be morning star The dates of greatest brilliancy and of greatest elongation are respectively March 18th and April 23rd, and the apparent diameters will not differ much from those of January 6th and December 2nd.

It should be noted that prior to the date of the greatest eastern elongation, and subsequent to that of the greatest western elongation, Venus presents the gibbous phase, that is, while the apparent diameter is diminished, more than one-half of the visible surface is illuminated.

◆

Word Blindness.

It is scarcely open to question that all education should be individual, but unfortunately this requirement cannot be met in our crowded schools. The State is compelled to require a definite amount of knowledge from all engaged in the same course. The difficulties to which this may give rise are illustrated by the following stories of pupils, who despite earnest endeavor could never learn to write correctly, or to read fluently, or to pass the examinations provided for the lowest classes, although some of them are able to accomplish important scientific work. A perfectly healthy fifteen-year-old girl, one of the best pupils of the highest class of a German school, could not spell correctly either German or foreign words, either from dictation or from memory She could write single characters perfectly, she could also read a single series of musical notes, and play the violin by note, but she could not read piano music. The difficulty was that she was unable to impress the picture of the word on her memory. By the employment of a great number of aids to memory she succeeded in making much progress, but she continued to make the most incredible errors in writing, which sharply contrasted with the general excellence of her work at school. She could not read fluently, because the image of the word was not present to her memory.

The girl's grandmother, a highly-educated woman, her great-uncle, and a son of the latter exhibited the same defects. Each of the men wrote a number of scientific works, but the spelling had to be corrected by others.

In this case, therefore, this same defect, which the English call "word blindness," appeared in four members of one family. As we know that the brain contains a special center for the memory of words, we must conclude that the entire absence of this elementary faculty in persons otherwise of good mental equipment, must be caused by a defect of this small part of the brain. As such persons cannot satisfy the requirements exacted in the lowest classes, they are in danger of never reaching the higher ones. In London, one case of word blindness was found among each two thousand school children With proper appreciation of the conditions, it should be possible to carry on the education of such a child if otherwise intelligent. This, however, cannot be done by the school, it must be accomplished by the parents or by benevolent societies.—Umschau

To Our Subscribers.

We are at the close of another year—the sixty-fifth of the SCIENTIFIC AMERICAN's life. Since the subscription of many a subscriber expires, it will not be amiss to call attention to the fact that the sending of the paper will be discontinued if the subscription be not renewed. In order to avoid any interruption in the receipt of the paper, subscriptions should be renewed before the publication of the first issue of the new year To those who are not familiar with the SUPPLEMENT, a word may not be out of place. The SUPPLEMENT contains articles too long for insertion in the SCIENTIFIC AMERICAN, as well as translations from foreign periodicals, the information contained in which would otherwise be inaccessible. By taking the SCIENTIFIC AMERICAN and SUPPLEMENT the subscriber receives the benefit of a reduction in the subscription price.

◆

The trials of the new German improved "Dreadnought" "Westfalen" in the North Sea are stated to have been highly satisfactory. She developed 24,000 horse-power and attained a speed of 20 knots, compared with the 20,000 horse-power and 19-knots stipulated for in the contract with the Weser yard.

Correspondence.

THE FARCE OF OUR MILITARY MANEUVERS.

To the Editor of the SCIENTIFIC AMERICAN:

The results of the recent Boston maneuvers led an enthusiastic militiaman to inquire, "What's the matter with the militia?" As far as I know, an answer has never been attempted

The writer participated as a regular officer in the Manassas maneuvers of 1904, and later served in the New York State troops. He has had occasion to view military maneuvers both from the standpoint of a regular and from that of a militiaman. In other words, he has maneuvered on a full stomach when physically fit, and when the work imposed upon him was little more than that which regularly befell his command, and he has taken part in military encampments when fresh from an office desk, unhardened to tramping, exposure to sun, rain, heat and cold, and the coarse, half-cooked food at which his stomach revolted.

Field instruction as now imparted consists of a senseless, unnecessary physical tax upon the health and strength of our militia. Nothing but the enthusiasm, the nerve, the gameness, of our citizen soldiers enable them to stand up under the work required of them, and enable them to perform duties which no regular officer would expect or require of his men, seasoned and hardened as they are, unless matters of the gravest import were at stake. In fact, I doubt if even the splendid discipline of our finest troops could stand such a test, for men experienced in military matters know that empty stomachs are not easy to reason with, and they certainly do not prompt blind obedience.

The armory affords but one form of instruction, and that form should be perfected as nearly as possible, and too much interest cannot be created in the organization, in order that the necessary tedium of drill may not drive the men away The day of tin soldiery, of strutting about in feathers and gaudy colors, has passed.

The fault then, as I see it, is not with the militia nor the present system of armory training, which does well enough. The fault lies in the system of field instruction, as conducted by the War Department of the United States of America.

No one denies that maneuvers when properly conducted afford splendid training for the troops engaged therein, for any large assemblage of troops is certain to yield valuable experience to men as well as officers But there are many ways of conducting maneuvers, and the wrong way is the one people find fault with.

Thoroughbred colts, however carefully bred for speed, require hard training and severe work to win on the track, but do trainers take likely animals and gallop them under great weight until every limb of their bodies aches, until their backs, unaccustomed to the saddle, blister and gall, until they become foot-sore and fall from exhaustion? Are these colts then dragged to strange quarters, exposed to the elements, and fed on sour corn and ill-prepared food? No. Their food is carefully prepared, and they are comfortably housed. It is only after they are seasoned that serious work is imposed upon them, and that great exertion is exacted of them They are but animals after all. They are creatures of flesh and blood, and there is a limit to their endurance. And so is the poor militiaman an animal of limited strength, though this fact has been lost sight of on the occasions known as "military maneuvers." The fact remains as true now, however, after the Manassas and Boston affairs, as it did before, for our War Department cannot change nature, nor can it reasonably hope to make a nation of seasoned war material by periodically overtaxing and maltreating a handful of citizens, who in their military zeal crowd up to the sacrifice of the maneuvers.

Did I say that these men were maltreated? Well, they are, for I have seen them with my own eyes trudging over the heaviest roads, weak and worn, with tender, bleeding feet bound with their handkerchiefs, while the relentless sun beat down upon their dizzy heads. I have seen them sweltering in stale clothes that stunk with the sweat of days, and no provision made to give them a change of clothing. I have seen them crawl like filthy animals from under insufficient covering to take up the labors of an endless day, filling their stomachs with ginger pop and doughnuts, while the nearby regulars, warm and dry, breakfasted on good hot coffee, bacon, hash, and bread Is it not pitiful to think that these poor fellows are misled into believing that such is the life of a soldier?

How can men under such conditions profit by the object lessons intended for them? The events, in which they play a sad part, are as non-understandable to these poor militiamen as ignorance and folly can make them. They flit through their weakened minds like troublous dreams. A waking dream it is, however, for seldom is the citizen soldier allowed to drown his troubles in sleep, to recuperate his depleted strength in repose. The night brings the dance of guard duty, the din of the camp added to by numberless officers who rate their ability by the amount of noise they can make, render sleep a foreigner to the militia camp.

Such, then, are some of the conditions which repeat themselves maneuver after maneuver. Much thought and time are spent on plans of attack, on entraining and detraining the troops, on testing the water supply and inspecting pits, but having lured the guardsman to the camp, little time is spent on his personal instruction.

He is taught not to shoot at his friends with real charges, and asked to march, march, march, day and night without food, without rest, without the slightest attention to bodily cleanliness, all of which are fundamental in the preservation of health and sanitary conditions.

Having criticised and condemned the present method of conducting maneuvers, it is only fair to answer the question, How can the militia be really benefited by field maneuvers?

In the first place, the time usually allotted is absolutely insufficient to permit of any real benefit to the militia, for the militiaman is not physically fit to stand the work of field movements on a large scale. Before such exertions are required of them, they should have at least a week or ten days to accustom themselves to camp fare and field conditions, to learn to make themselves comfortable in camp and bivouac, to toughen themselves gradually With each command of militia should be camped enough regular troops to supply each militia company with a competent cook, to instruct the men in the preparation of their rations To each company should be detailed several regulars, to instruct the men in tent pitching, camp police, how to keep themselves and their equipment clean, how to make comfortable pallets on hard ground, how to secure rest at night, in matters of camp sanitation and numberless other things which experienced soldiers regard as necessary Such instructions would indeed be valuable, for these are things which are not to be learned in the armory

For the first week or ten days in camp, tedious drills and ceremonies should be dispensed with, and instead the men should be given light exercise in the form of short marches during the cool of the day, so as to allow them to adjust their packs, break in their shoes, and harden their feet to marching Upon returning from such marches, they should be required to wash themselves and change clothing, and then be allowed to rest. Dress parades, reviews, and such displays should be dispensed with. They do not instruct the men After the machinery of the camp is in good working order, and the quartermasters and commissaries have distributed their supplies, after the sore feet and weaklings have been weeded out, night attacks, forced marches, picket duty, etc., may be indulged in with some advantage to the field officers at least, and without very great punishment to the men of their command The men will by this time be in a physical condition which will permit of discipline, and will not be broken down and demoralized, so that they will go home utterly exhausted, and with the idea firmly rooted in their minds that the mobilization of a large body of troops means confusion and neglect of all semblance of the order and the precision which have been drilled into them by their officers at home. I may here say that my experience has been that it takes a number of drills after an encampment to get the men back in shape, so demoralized do they become under the influence of the so-called field discipline, which should be, if possible, even greater than garrison discipline.

Tactical movements as maneuvers can be instructive only to field officers and their staffs, the other participants are not in a position to follow the movement of the army as a whole Therefore, since the junior officers and men must remain necessarily in more or less ignorance concerning the movements of the army, unless something is devised for their instruction and benefit, the maneuver, so far as the great mass of participants is concerned, is a useless farce. This being so, every move and every order emanating from the commander of a maneuver army should have in view the instruction of the individuals of the army, and no move should ever be made which would sacrifice order and discipline in the ranks, even to the tactical success of the commander

Now, then, it will be said that the militiamen cannot spare the time to follow out the above plan, that they cannot neglect their business, upon which they depend for a living; and that to require the militia to spend two or three weeks now and then in camp, would be to set up requirements which would discourage enlistment in the State organizations. This is an old argument, and apparently has some weight, but upon investigation it will be found that the average militiaman, under present methods, is rendered unfit for effective work for a much longer period than that actively spent in camp. Some of them, poor fellows, never return to work. Many more go to the hospitals and to their sick beds for weeks, and the demoralization of mind, due to utter exhaustion of the body, renders the majority of the remainder unfit for work for varying periods of time.

But suppose the militia could not be mobilized for two weeks, or better still, a month, every second year, so as to throw an encampment in every man's enlistment, is it not better to give up the present farcical, cruel, and demoralizing system of maneuvers, than to subject the militia to such senseless physical tests?

Even if such methods as now employed were capable of putting our citizen soldiers in fit physical condition, would they remain so indefinitely? Would they not be soft, and again unseasoned upon the advent of war? Is not the fact that our militia is demoralized and unfit for the slightest additional effort at the end of the maneuver periods ample proof that the present system is erroneous? There is but one correct answer to each of these questions and it is a crying shame for the sages of our War Department to take enthusiastic militiamen far more intelligent than the average regular soldier, eager to learn and unselfish in the devotion of their time to their State and subject them to hardships which regulars could not be expected to bear under similar circumstances.

As a regular, I have smiled and looked with scorn upon the disorganized and crippled ranks of our citizen soldiers in the maneuver field, but as a militiaman I have felt the indignities which earnest and willing men have borne in those exhausted ranks.

I say that the fault lies not with the militia far from perfect as it is, but with our War Department and those who conduct the field maneuvers. If their judgment were as faultless as the enthusiasm and willingness of the average militiaman is great, much good would result from field instruction

JENNINGS C WISE.

An American Demonstration of the Urban-Smith Process of Animated Color Photography

The evening of December 11th a demonstration was given in the concert hall of Madison Square Garden, New York city, of a new process of moving pictures in natural colors, which has been perfected during the last two years by Mr G Albert Smith of London, England A large audience was entertained for two hours with a considerable number of kinematograph views in natural colors These pictures besides being excellent reproductions of the original subjects both as to shade and color, were not so tiring to the eyes as the ordinary moving pictures, due probably to two reasons, viz, double the number of pictures thrown upon the screen, thirty-two in a second and the toning down of the light by the color screens

The new process is a modification of the Friesse-Greene process illustrated in the issue of this journal of October 9th last Instead of using three color screens—red green, and blue—in connection with two films, as does this inventor, Messrs. Urban and Smith have combined the blue and the green into a single blue-green screen One-half the pictures are taken through a red screen, and the other half through this blue-green screen The screens, of colored gelatine, are arranged so that each forms half of a revolving disk placed in front of the lens. The pictures are taken on a specially prepared film made panchromatic by means of suitable dyes. As a result of this there is scarcely any difference in the density of the two images made through the different color screens. A positive is made from the negative upon ordinary film When this is projected through the colored screens—each picture of course being projected through the same colored screen as that through which it was taken—the spectator sees the view in its natural colors, since the eye retains the color impression of the red, for example while the blue-green picture is being substituted for it and after the latter is in its place. The combination of these two colors produces white light in much the same way as three colors do this with the Ives process. The single film and single revolving screen in front of the lens is a great simplification of the Friesse-Greene two film process The pictures can be made with an ordinary machine with but few changes. The subjects shown varied widely, extending from flowers to animals and birds harvest scenes, military reviews waterfalls and surf etc. In all of these pictures the coloring was excellent and altogether true to nature Such colored pictures have been shown for some time in several large music halls abroad and they will soon be produced no doubt, in similar places in this country

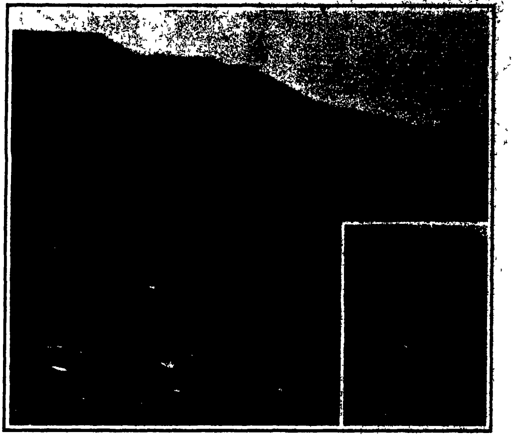
A sliding embankment on the Pennsylvania lines west of Pittsburg near Dinsmore Pa which had given trouble for some years, was remedied at a time when a new culvert was put through it by driving two small tunnels entirely through the embankment and filling them with riprap. The embankment is 30 feet high and is on a sharp curve on a hillside having a slope of 20 deg., down the face of which runs a small stream When the tunnels pierced the core of the embankment water gushed out for several hours in a stream large enough to fill a 12 inch pipe These tunnels keep the embankment drained, and no trouble has occurred.

AN AERIAL PASSENGER RAILWAY.

BY ROLAND ASHFORD PHILLIPS.

It is as easy now to ride in a bucket from the base to the very summit of the loftiest mountain chain in the Rockies, as to trolley across Brooklyn Bridge.

The station, showing the cables leaving the drum.



The bucket has just left the power house. An empty bucket is seen coming back.

To take this wonderful ride on the Sunrise Peak road, you leave Silver Plume and walk a few blocks to the aerial station Under this cover you wait for your bucket As it swoops down and stops, you step into it The man shuts the door and locks it secure A bell clangs, and you are off. The bucket swings away, and you hold tightly to the iron rim. The little depot with its crowd slips away below You look around. There are no confining walls—nothing but clear Colorado air Your sensations are comparable with those of a balloonist.

You begin to gather a bit more courage You look around. There to your right are towering [illegible], a dozen times as lofty and as massive as the tallest skyscraper In another direction are deep cañons, rocky gorges, and steep, verdant slopes. Still you go up Sometimes you clip the swaying tips of a monster primeval pine tree and again you are swaying over an all but bottomless cañon Then a broad green valley slips along below you, colored with myriads of wild flowers Now marked like some gigantic belt, comes the timber line The flowers give way to stunted brush and barren stretches of dull rock. And both of these in turn are soon hid from view [illegible] way. [illegible] ing half hour is [illegible]. The bucket [illegible] out upon the cold, snow-clad summit of the peak. At intervals fleecy clouds drift across your vision, [illegible] out the valley below.

You have gone to the sky in a bucket, you are standing above the clouds, two and one-half miles higher than New York city

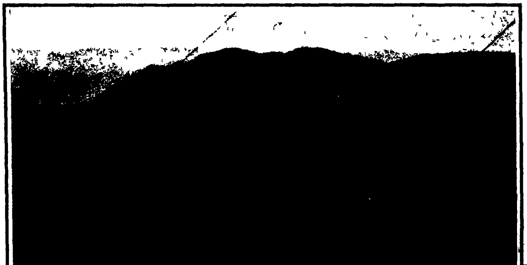
When the clouds clear away, you note the filmy line of cables stretching down, from tower to tower not unlike the silken web of some gigantic spider, swaying in the sunlight, finally to dip over a ragged shoulder of a ridge and disappear

The idea of these traveling buckets is by no means new particularly to readers of this journal, since the identical principle is in use throughout the mining world as a means of transporting ore from the mines to the mills. In some instances these are worked by gravity, and in others by motive power

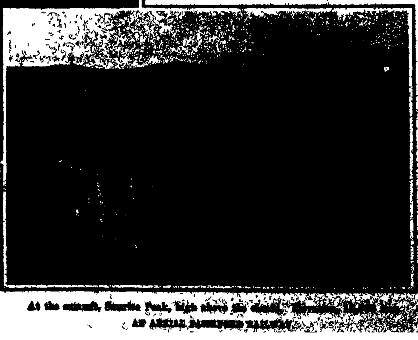
It remained however for a western engineer to utilize this system of carriers, not for business but for pleasure For a good many years Sunrise Peak was a noted attraction for the tourist, but all methods of reaching its lofty summit were crude indeed Confident of his success, the engineer interested a few wealthy men The aerial railroad is the result. In Italy this method of transportation is largely in favor, especially across bodies of water, but the Sunrise Peak line is the only one in America.

There are two main cables, the stationary and the

(Continued on page [illegible].)



This picture was taken about half way to the summit. Silver Plume looms in the distance The wagon road is seen winding up into the hills; also the creek, down the cañon of which the railway runs which connects with Denver



At the summit, Sunrise Peak, high above the clouds. [illegible]

AN AERIAL PASSENGER RAILWAY.

HOW YOUR EYEGLASSES ARE MADE.

BY [illegible]

[illegible] man ever had but one pair of eyes. Most men value them above all other senses. Yet is a man often careless of his eyes, neglecting the visit to the optician and the glasses which may improve and prolong his sight, and ninety-nine out of a hundred of him never think or ask, "Am I getting the best-made lens the market affords?" He takes what the optician gives him on faith. The hundredth man goes through a spectacle lens factory, and forever after he is extremely particular about his glasses. He finds out how difficult and how delicate an operation lens-grinding is. He knows how easy it would be to make an error.

First he sees the imported blank pieces of glass sorted by machinery before being ground—for greater accuracy Then he watches a workman attaching them with pitch to "blocks" and "shells," concave or convex pieces of iron of exact curvature, which are revolved in their mates with abrasive, to do the grinding. He notices that the more powerful the lens is to be, the smaller the shell and block, and the less the number of blanks it will accommodate. Hence the increase in price of strong lenses over weak ones. Wandering through the labyrinthian corridors in the basement of a great factory, and seeing the thousands and thousands of pairs of shells and blocks used for spectacle-lens grinding alone, he stops to wonder at the science and the knowledge which devised this enormous number of possible curvatures Here glass working and metal working join hands. The alliance is vital, since the curve of the lens depends on the curve of the shell and block, the perfection of which means the perfection of the original lathe.

Fig. 1.—Fine grinding of a pair of eyeglass lenses.

Fig. 2.—Lenses cut but outer rim not broken off.

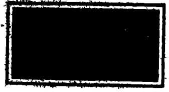


Fig. 3.—Centered lenses, showing center mark and reflection of this mark below it.

Fig 4.—Polished and edged lenses of a pair of eyeglasses.

Fig. 5.—Lenses entirely finished, drilled, edged, and ready for the stock room.

Fig 6 Improperly polished lenses, the black spot and band showing portion which has remained rough

The sightseer may walk through aisle after aisle of room after room, filled, in long, long ranks, with hundreds of grinding machines. He will see machine tenders, each with his set of machines to watch, keeping each set of lenses supplied with abrasive, changing blocks and shells from the rough grinders to the second grinders, from the second grinders to the fine grinders, and from the fine grinders to the polishing machines, where felt, carefully mounted on block or shell of proper curvature, and rouge, take the place of iron and emery, working out the last tiny abrasive mark and leaving the lens with a highly glossy surface, perfectly polished. He will watch the "picker" detaching lenses from the pitch with a pointed tool and may perhaps ask to try it (it looks so easy) and may well break up several dollars' worth of lenses in attempting to imitate the skillful movements of the trained workman. He will watch the reblocking of the lenses, this time in the shell, or upon another block, if the lens is a double convex, see the whole range of operations repeated, and note the even greater care taken now, for it is no longer *only* glass which is being ground, but a partly finished lens, the cost of which has far exceeded the first cost of the raw materials. But he will not be able to watch any individual lens through all of its operations. Clock hands mark four and one-half hours for each of the rough, second, and fine grindings, and as long for polishing—more than two days to complete any one lens. Cylindrical lenses require even longer—five hours for each grinding and seven for the polishing

Centering the lens. This operation is highly important; for on the ink spot placed on the center of the lens depend the mechanical and optical properties of the finished lens.

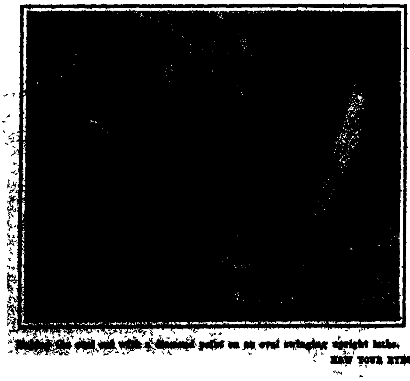
There is something uncanny about the grinding machines. To grind any glass evenly and truly requires more than one movement. While the shell or block revolves the axis of the companion fitting it nutates back and forth and revolves also, so that each lens continually changes its angle with the grinding or polishing surface With the cylindrical grinding machines there is no revolution of the grinding surface, but a constant shifting back and forth which accomplishes the same purpose One machine would not impress, ten would hardly get a curious stare but thousands and thousands, all nodding and bowing, certainly command attention

The visitor will hear something about the names and kinds of spectacle lenses. For instance a periscopic lens is a meniscus, or a convexo-concave lens. Periscopic means "all seeing," and the use of this form in eyeglasses not only gives the eyes a wider angle of view than does the plano lens, but better accommodates the sweep of eyelashes, decreases reflections from behind and when the periscopic curve is deep, maintains all parts of the lens as nearly as possible equidistant from the pupil of the eye, no matter in which direction the eye itself be turned

The ordinary two-curve or sphero-cylinder lens used for the correction of hypermetropia or myopia and astigmatism at the same time having one side of the lens ground to the section of a cylinder and the other side to the section of a sphere obviously cannot be made periscopic if the spherical curve be convex, nor deeply periscopic if the spherical curve be concave Yet the advantages of a deep periscopic glass are as great with the sphero-cylinder lens as with any other

How is the problem solved? The solution was known long ago—the toric lens—but only recently has its successful manufacture been possible A spherical lens has the same curvature measured in any meridian A cylindrical lens has no curvature in one meridian, and its greatest curvature in the meridian at right angles to the first

A sphero-cylindrical lens has a spherical curve on one side and a cylindrical curve on the other A toric lens is one having two different degrees of curvature in two meridians at right angles to each other on the same side of the glass. These two curvatures have the effect of a sphero-cylindrical



[illegible] the oval cut with a diamond point on an oval swinging upright lathe.

Drilling holes with diamond drills for rimless glasses.

HOW YOUR EYEGLASSES ARE MADE.

lens. The difficulties of the manufacture of toric lenses are enormous, as may be imagined, requiring special machinery to grind two curves at once on one side of one piece of glass. Only in recent years have such lenses been commercially possible. These grinding machines have meant the expenditure of thousands and thousands of dollars and of years and years of time.

Ground, the lenses go to the cleaning room, where, in wooden trays, they are soused and soused again in ten different baths, acid and water, and alkali and water, and soap and water, and repeat. Finally they are plunged in a bath of rouge, which leaves the wooden trays dyed the familiar red of the optical factory, and with a film of rouge on each glass for the final hand polishing and cleaning

So far the glass has been merely glass, raw material in various stages of manufacture. Now it is a lens. Before it goes further in the tedious costly process of making raw glass into an aid to eye sight, it is rigidly inspected

Inspection is for striæ (streaks), for air bubbles, for picker's scratches, for grinding scratches, for failure to "polish out," for too great thickness or thinness, for cracks, for breaks, for nicks, and for "target polishing," or polishing in rings. The girls who inspect for defects and for quality, who decide whether a lens is of first quality or not, become extremely expert. They see things in an instant which you may not be able to see even when pointed out Every sphero-cylinder or cylinder lens must cut a circle thirty nine millimeters. Its axis can then be ground at any angle for a normal eye. Larger lenses are supplied on order In the spherical glasses the inspection test must not show any defect within an oval thirty-nine by thirty millimeters, nor any serious defect, such as chip or striæ, beyond that size.

After inspection, a series of operations, bewildering in the dexterity with which they are accomplished, the lens is centered A girl fits the glass on the centering instrument, takes a swift look through an eyepiece, sees that a cross hair behind the eyeglass and a cross hair behind the eyepiece of her instrument are in line, and "click," a little ink-spotted pointer has touched the center of the lens, the optical center If the lens has a cylindrical curve, and consequently a major axis three ink spots are made upon it, one for the optical center and one at each end to show the axis.

For axial determination, the instrument is accurate to within one-half a degree The lenses are gaged for thickness, and sorted to size, and then gaged and sorted for actual area, lenses are "two eye," "one eye" "0 eye," "00," "000," "0000 eye," and finally "jumbo" in size, and each must be gaged to see what size it will cut.

Spherical lenses are usually finished at the factory, edge-ground and packed ready for use, and, since a spherical lens has no axis, it can be cut with the long axis of the oval in any direction to the shape of the ground and polished blank But the cylindrical lens, the sphero-cylinder, or the toric, must be left unfinished as to edge, except for special order, since the angle the axis of the cylinder curve is to make with the astigmatic eye is important.

If the lens is to be edge-ground, the next operator upon it fits the lens over a size gage upon the table of a little machine, turns a handle, and behold, a tiny diamond cutter has oval ringed the glass with a scratch the shape of the finished lens. Another girl breaks off the rough edges with pliers and, perhaps a rough pair of iron shears. To see her surrounded with splinters and tiny spikes of glass all over her lap and bench, you would imagine she was in imminent danger of injury, but cuts are rare even with the thickest and heaviest of lenses.

For rimless eyeglasses or spectacles the lens must have holes drilled in it. It goes to a girl with a drilling machine and diamond-pointed drills. As the tough material is bored, a steady stream of cleanly odorous camphorated turpentine plays upon the glass and the drill, and the little automatic machines, each with its impassive feminine watcher, turn out lens after lens with one or two tiny smooth-edged holes at the ends, ready for the next operation

More washing and cleaning follow, and then edge grinding, a matter of wonderfully ingenious machinery, by which the rough-chipped edges are made smooth and the lens, so far as working the glass is concerned, is finished

Then this product of many operations is focused, much as the elements of a photographic lens are focused, by a girl with a special focusing camera, wiped again, packed, labeled, and stocked. Two hundred and twenty-five gross pairs, or sixty-three thousand lenses, are so finished every day in one big factory

Nearly a million pounds of optical glass are made into eyeglasses in this one factory every year. It takes thirty tons of emery to grind, and twenty tons of rouge to polish this product. It requires five thousand yards of towelling every year to wipe it clean. For every unedged lens, there are forty-nine operations, for every edged lens, sixty-eight operations. A spectacle lens is simple to look at, but after you have visited the factory, you will know it for what it is—a very complex thing.

FLIGHT WITH FLAPPING WINGS.

Human flight by flapping wings is impossible for several reasons, chief among which is that Nature has failed to furnish us with the anatomy or the muscular strength which are necessary for flight of this kind

Copyright 1909 by Underwood & Underwood.

Rear view showing the wing framing and the tail.

It is evident that the motive power for the machine herewith illustrated is to be furnished by the arms of the operator, and the movements when the body was in horizontal flight, would consist of a vertical oscillatory movement of the arms when stretched to their full extent. The power for lifting and propelling of a man and the machine, whose weight would be at least two hundred pounds, would therefore have to be furnished entirely by certain muscles of the chest and shoulders, which are rarely brought into strenuous use, and are feeble compared with other muscles of the body

Furthermore, with the slow rate of oscillation of the wings of which a man would be capable, their area would have to be very large, and their weight would of course increase rapidly in proportion. Prof. Langley pointed out that the difficulty of flying with flapping wings increases rapidly with the increase in size and weight, this being due to the mathematical law that the area in bodies increases as the square of their dimensions, while their weight increases as the cube. He pointed out that "the larger the creature or machine, the less the relative area of support may be (that is if we consider the mathematical relationship, without reference to the question whether this diminished support is actually physically sufficient or not), so that we soon reach a condition where we cannot imagine flight possible. Thus, if in a soaring bird, which we may suppose to weigh 2 pounds, we should find that it had 2 square feet of surface, or a rate of a foot to a pound, it would follow from the law just stated that in a soaring bird of twice the dimensions we would have a weight of 16 pounds and an area of 8 square feet, or only half a square foot of supporting surface to the pound of weight, or if flight is possible in the first case, it would appear to be highly improbable in the second. The difficulty grows greater as we increase the size, for when we have a creature of three times the dimensions we shall have twenty-seven times the weight and only nine times the sustaining surface, which is but one-third of a foot to a pound. This is a consequence of a mathematical law, from which it would appear to follow that we cannot have a flying creature much greater than a limit of area like the condor, unless endued with extraordinary strength of wing."

Copyright 1909 by Underwood & Underwood.

The frame is of aluminium and covered with balloon cloth. There is no motor. The designer hopes to fly by man power.

FLIGHT WITH FLAPPING WINGS.

To fly with the machine herewith illustrated would call for an expenditure of horse-power far beyond that which the strongest man on record ever possessed. It is doubtful if the average man is capable of exerting more than a quarter to a third of a horse-power continuously. It is true that, in supreme moments of effort, and for a very brief period, athletes may exert as high as one horse-power or a little over. The motorless aeroplane, or glider, is the only successful medium of human flight. Flapping wings are clumsy, difficult to construct, uneconomical in operation, and, according to present knowledge and experience in the subject, they form a wholly impossible means of human flight.

Depth of the Gulf Stream.

In Lieut. Pillsbury's examination of the Gulf Stream at various points from Hatteras southward, he found that the stream reaches to the very bottom in some places and tabulated its velocity at different depths. His results, as well as a review of the whole field of Gulf Stream investigation, are found in appendix 10, report for 1890, of the United States Coast and Geodetic Survey. It must not be inferred from the foregoing that all ocean currents extend to the bottom of the sea. Many instances are at hand of ocean currents extending to great depths. For example, Admiral Irminger, of the Danish navy, found that the northwesterly current in latitude 25 deg. 04 min. N., longitude 65 deg. 41 min. W., prevailed to a depth of 290 meters; Commander John R. Bartlett, United States navy, found a current in the Windward Passage to the depth of more than 800 fathoms (1,460 meters), and concluded that it reached to the bottom, between Key West and Havana the stream was measured in 1860 to a depth of 600 fathoms (nearly 1,100 meters), and was found to be only 10 per cent less than at the surface.

It is well established that the Gulf Stream loses in depth, temperature, and velocity, and gains in width, especially after passing Cape Hatteras, until the 40th meridian it becomes a drift current, reinforced on its right flank by the powerful Bahama current. Various measurements for temperature show that the Gulf Stream is shallower than its northeastern extension beyond the 40th meridian. Thus Commander Chimmo, R. N., commanding H. B. M. S. "Gannet," during the summer of 1868, found the warm water of the Gulf Stream to be less than 50 fathoms deep in latitude 44 deg. 03 min. N., longitude 48 deg. 07 min. W Ten degrees to the eastward the warm water had deepened to 100 fathoms or more and in latitude 43 deg. 48 min. N., longitude 37 deg. 47 min. W, the warm water was found to extend down about 250 fathoms. Observations made on board H. B. M S. "Porcupine," during the summer of 1869, showed remarkable depths in the Gulf Stream drift, as follows In latitude 59 deg. 35 min. N., longitude 9 deg. 11 min. W., the warm water was found to extend to the very bottom of the sea, 767 fathoms (1,409 meters); at Rockall the warm drift was found to reach down 900 fathoms below the surface, and similarly again in latitude 47 deg. 38 min. N., longitude 12 deg. 08 min. W. At the last-mentioned observation spots the warm water was found to be underrun by a polar current at depths of more than 800 fathoms. A similar phenomenon is often observed near the Grand Banks where the Labrador current dips under the Gulf Stream at comparatively shallow depths, 50 to 100 fathoms.

Daniel's Comet.

The comet discovered by Mr. Daniel of Princeton Observatory has received considerable attention throughout the country. Dr. H. C. Wilson of the Goodsell Observatory, and Prof. E. B. Frost, Director of Yerkes Observatory, have both sent communications on the subject to Harvard College Observatory. Furthermore, Dr Ebell of Kiel has computed an ephemeris. From the photograph which has been made at Yerkes Observatory it seems that the comet has no stellar nucleus; a short tail is suspected.

THE BABY MUSK OX AND THE ALASKAN BEAR OF THE NEW YORK ZOOLOGICAL GARDENS.

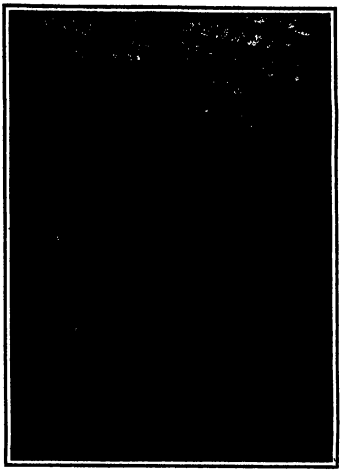
BY WALTER L. BEASLEY.

Through the efforts of Director W. T. Hornaday of the New York Zoological Society, New York has acquired two most interesting new animals—one a baby musk ox, and the other a giant Alaskan brown bear

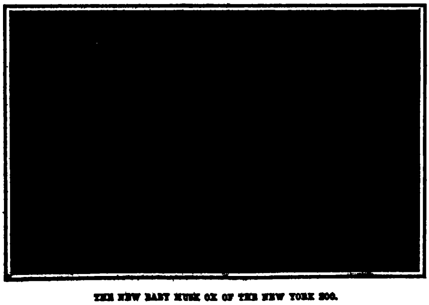
Although the musk ox is a typical polar animal, this is perhaps the only specimen to be found in captivity Whether our climate will so far affect the animal's health that it will perish, remains to be seen. This particular specimen was captured on Melville Island, six thousand miles from the Zoo. The price paid was $900. The animal is about six months old, and in splendid physical condition. The entire body is covered with a dense mass of fine brown wool. Across the forehead is a broad band of white, and on the back a light gray saddle mark. A thick mass of wool hides the short horns. In time these horns will grow until they meet at the center of the forehead. When fully grown the whole top of the head will be covered by a pair of horns considerably flattened at the base, meeting in the center of the forehead, thence sweeping downward over the edge of the cranium, close to the cheeks, and finally recurving upward before coming to a point. The animal illustrated is about 3 feet long, nearly 2½ feet in height, is about half grown, weighing 190 pounds. A full-size adult male stands 4 feet 5 inches high at the shoulders and is 6 feet 7 inches in length, weighing about 1,200 pounds. The species shown in our photographs, from the marked characteristic of the large whitish patch on the face and saddle mark on the back, has been named by Mr R. Lydekker, of the British Museum, *Ovibos Moschatus Wardi*, in honor of Mr Howland Ward, the natural history dealer of Piccadilly, London, from two types of a mounted male and female from East Greenland, in his possession. The other form or species of the musk ox, *Ovibos Moschatus*, is confined mainly to the Arctic Barren Ground regions east of the Mackenzie River, and formerly thought to have had a continuous distribution westward across Alaska.

Of the 5,530 living animals in the New York Zoological Park, one of the most remarkable is the great Alaskan brown bear Ivan. This colossal animal belongs to the species *Ursus dalligyas* Merriam, and was captured at Moeller Bay, Alaska Peninsula.

The writer was able to obtain a very striking picture of the giant Ivan, standing seven feet in the air with uplifted front paw, by venturing inside the inclosure with an attendant A tempting fish coaxed the big animal to assume an upright pose. Ivan recently gave a practical exhibition of his astonishing strength and vigor by tearing out a panel of the heavy steel bars that separate his quarters from those adjoining and engaging in a fierce battle with a hated rival. In ten minutes the monster bear wrenched and trampled down the barricade of steel bars as if they had been made of reeds. It would have taken six men an hour with block and tackle, sledge hammers, etc., to have accomplished such a damage. The enraged giant fought with his antagonist until finally clubbed off by the keepers. Ivan's long shining and shaggy brown coat converted into a rug would be worth nearly one thousand dollars. Ivan is one of the few living examples of the fast disappearing species of the giant brown bears of America in captivity, a species especially interesting as possessing some very extraordinary, intelligent habits. In his distant Alaskan home Ivan practised the art of salmon fishing. As soon as the salmon begin to enter the streams in July, from the sea, big brown bears of his species make fishing their chief business. Both the old male and female fish for salmon in order to furnish a plentiful supply to satisfy their own enormous appetites and those of their young. The cubs do not attempt to fish, but stay on the bank and receive contributions tossed up by one of the parents. The she-bear stands upright, and wades in water even up to her back, going very slowly with the current, watching the water, and scarcely making a ripple in it. She holds her arms down at her sides with hands or paws spread, and when she feels a salmon coming up against her, quickly clutches it with her paws, and throws it out on the bank to the expectant cubs. After supplying the cubs she tosses up a pile for herself. The last fish she puts in her mouth, and goes ashore to enjoy her feast.



IVAN, THE GREAT ALASKAN BROWN BEAR OF THE NEW YORK ZOO



THE NEW BABY MUSK OX OF THE NEW YORK ZOO.

Artificial Petroleum.

The origin of petroleum is still an object of much dispute among savants, some attribute it to inorganic sources, others to organic In America there is an inclination toward the latter solution of the problem, at least so far as concerns the petroleum of the New World, for the layers of schist which carry it always contain the *débris* of diatoms, foraminiferæ, the skeletons and scales of fish, etc.

Impressed with this latter detail a savant (of whom the name is not given) has, as a result of many trials, made it seem certain that petroleum was formed by a sort of distillation of extinct sea fish. According to indications, states the Revue des Eclairages, manufacturers should collect a large number of fish and should have them distilled. They ought then, moreover, to obtain a result something like that from the following first trial

The savant then conceived the idea of mixing the fish with a large quantity of salt. The novel experiment was made tentatively, the fish were strung upon cords and brought into a large retort, where they were mixed with a quantity of sea salt, the whole, upon distillation, gave a petroleum of excellent quality, which could be used for the lighting of buoys. We have no information, unfortunately, about the economy of such a method of procedure, and do not know moreover, if the company which has made this trial has been able to continue with success which justifies commercial development.

We confess that we are a little skeptical regarding this novelty It may well be that there was obtained by this procedure an oil capable of burning, that may be granted but was it petroleum? It might be well to preserve this idea, which would be of some use when the natural suply of petroloum is exhausted

The Current Supplement.

"How Sponges Are Gathered and Artificially Grown is the title of an article by Newton Forest which opens the current SUPPLEMENT No 1773 Mr R M Strong s excellent comparison of gasoline and alcohol engines is continued The first experiments made in aviation were desultory, and were made without the help of any well established rules Hence it is that the fundamental principles and mechanical properties of fluids were not as well understood as they should be To that end institutions have been established in Europe for the express purpose of obtaining a really scientific knowledge of the air and propellers and plane surfaces One of these institutions is described C G Derrick reviews the methods in current use for waterproofing concrete structures Capt. A C. Knowles writes on the Army Signal School and its work. Whether the wax bust purchased by Dr Wilhelm Bode for the Kaiser Friedrich Museum at Berlin is really the work of Leonardo da Vinci as is claimed or of a modern craftsman, is discussed The evidence *pro* and *con* is impartially given Under the striking title "The Blood of Plants' Mr Victor Graef writes on some modern botanical researches The reappearance of Halley s comet renders particularly timely Mr Arthur Stanley Eddington's paper on light pressure and comets tails Dr Alfred Gradenwitz contributes an excellent article on wireless transmission of diagrams handwriting, and photographs. The startling success of Mr Louis Brennan with his gyrostatic car lends peculiar interest to an article by Mr Horace B McCabe on the principles and applications of the gyrostat

Cooling Tower Practice.

In an article on cooling tower practice which appeared in the Electric World some little time ago the author states that tests on both open and closed types of towers, under various hygrometric conditions, have shown that, with an average range in temperature extending over several days of from 140 deg to 170 deg F., the fall in temperature obtainable has resulted in outflowing water of from 90 deg to 60 deg F with atmospheric temperatures between 55 deg and 85 deg F, and hygrometric conditions ranging from 30 to 50 per cent of normal saturation An open type tower capable of cooling from 400 to 600 gallons of water per minute as dependent upon its special construction will be roughly 20 feet by 20 feet by 40 feet or 45 feet for cubical contents and will have at least six so-called drip pans or retarding surfaces in its make-up The cost of such a tower with a capacity of 400 gallons per minute would range between $1 200 and $1,500 and in general each additional 100 gallons per minute capacity increases the cost by approximately $200 The closed type costs from three to four times that amount for installation and the additional increases range at about double the price for the open type. In cost of operation about $2 per day will be required for maintenance of the tower and for fuel and water for operation of fans pumps, etc. If water costs 6 cents per 1 000 gallons or more, the author maintains that it pays to erect the cooling tower if the total water lift does not exceed 80 feet.

* * *

The only export tax in Mexico on minerals or mineral products is on gold and silver All other products of the mines are exported free except for a nominal customs charge at the port of export.

RECENTLY PATENTED INVENTIONS.

Pertaining to Apparel.

COMBINED SOCK AND GARTER.—L. O. Gitchell, New York, N. Y. This garment fastener comprises a combined sock and garter arranged to insure correct support of the sock on the leg and to allow ready closing and opening of the garter, the latter being for this purpose permanently attached to extension flaps formed integrally on the upper end of the sock at the sides thereof.

RACK.—G. H. McGibbon, New Glasgow, Nova Scotia, Canada, and A. S. Redland, New York, N. Y. One object of this invention is to provide a simple and inexpensive and compactly built rack for displaying and preserving articles such as garments and the like which can be easily taken apart and packed into a small space, and in which the articles can be protected from dust, moisture and so forth.

Electrical Devices.

BINDING POST.—I. Steinberger, New York. Mr. Steinberger's invention comprehends a post having a central stem encircled by a spiral spring of metal and adjacent to the ends of this spring clamping plates arranged in pairs, the plates of each pair being pressed together by the action of the spring and the outer edges of the clamping plates being slightly curved to facilitate the entrance of the wire therebetween.

Of Interest to Farmers.

SELF-BINDER ATTACHMENT.—F. Pennington, Westhope, N. D. The inventor has means for depositing the bundles of grain delivered from a self-binder in shocks while the machine is in motion. An object is to provide means whereby the bundles of grain as they are delivered from the self-binder may be held together in shock form and at the will of the operator deposited in shocks.

CORN-PLANTER.—G. M. Gorman, Anamosa, Iowa. The inventor employs a marking device for seed-planters whereby the rows of hills are maintained in parallel lines and equidistant, and provides a mechanism for accurately operating the marking devices, which mechanism may be raised and lowered out of and into operative contact with the ground conjointly with the planting device.

FRAME.—L. B. Stetson, Bellevue, Wash. This invention relates more particularly to adjustable frames such as are adapted to be used in the cultivation of plants such as tomato vines and the like, and which consist of uprights adapted to be driven into the ground and having arms pivotally secured thereto, means for holding the arms extended, and supports removably arranged on the arms of the uprights.

GRAIN-CUTTER.—I. Clark, Greenfield, Ind. The cutter is for use in connection with binders. The object of the inventor is to provide a combined cutter and binder whereby the grain may be bound into bundles while in upright position as it is cut from the ground. Means provide for dividing the grain as it is about to be cut and supporting said grain after it is cut in upright position and transporting it to a binder mechanism while still in the upright position.

CORN-RACK.—J. S. Winton, Milford, Iowa. In the present patent the invention is an improved rack and belongs to that class of such devices in which a number of corn ear impaling pins project from a support and sustain the ears in spaced relation and at known points during the period of curing, storing and testing.

EGG-TESTER.—Evelyn Laing, Bronxville, N. Y. By this device eggs may be conveniently inspected at the outside of the usual egg testing box. The box has egg-seating openings in the top and is provided at the side with a door having a mirror on its inner face, the door being hinged to swing downwardly and outwardly to a position to reflect the light passing through the openings.

Of General Interest.

WELL-TUBING AND MEANS FOR CONNECTING SECTIONS THEREOF.—G. A. Pittman, Dawson, Neb. The object here is to provide a tube of any length from vitrified clay formed in sections before baking the same, and also provide clamping means for joining the tube sections together endwise, thus producing a practical lining which may be placed in a well bore or removed therefrom with the same means used to insert and remove iron lining tubes.

ARTIFICIAL HAND.—W. A. Hennessey, Ashland, Wis. In view in this invention are the following objects: To provide means whereby the fingers of an artificial hand may be caused to fold and to grip an object to lift the same; to provide means whereby the fingers of an artificial hand may be maintained in a released position, and to simplify the construction so that the hand may be automatically operated.

DRY YEAST COMPOUND.—J. F. Yost, Arkansas City, Kan. The more particular purpose of the invention is to provide a carrier for certain yeast compounds originally prepared in the form of a liquid and afterward dried. The product consists of vegetable pith and a yeast compound, the pith being in the form of small particles and the compound being coated superficially upon the particles.

FOLDING CRATE.—F. C. Miller, Chehalis, Wash. The object of this improvement is to provide a crate or like receptacle, having its parts arranged for convenient erection or folding into a flat package and locking the folded parts in place. It relates to crates, such as shown and described in the Letters Patent of the U. S. formerly granted to Mr. Mary.

SELF-CLOSING BOTTOM FOR WELL-STRAINERS.—J. A. Pollard, Oakland, Miss. In the present patent the invention relates to self-closing bottoms for well-strainers, which are adapted to be attached to a well-strainer of any suitable type and to be lowered into a well, together with a strainer, by means of a force-pipe, the latter being afterward removed.

SYRUP PERCOLATOR.—F. De Clercq, New York, N. Y. The aim of the invention is to produce a percolator in which sugar can be readily dissolved without coming into contact with the air, and from which the syrup may be readily withdrawn from the syrup compartment beneath. A further object is to provide a filtering bottom for the sugar compartment.

DRAG.—J. Bladholm and A. Bladholm, Marshall, Minn. The invention is an improvement in drags for smoothing and shaping roads, etc., and has in view such a device embodying elements of strength and durability, and primarily built of standard cross-sectional forms of rolled steel, the drag being capable of being drawn either in alinement with the road or at an angle thereto, and operating to shear the dirt off rather than tear it apart.

ENVELOP.—L. C. Van Riper, New York, N. Y. The envelop is provided with an ungummed flap which may be held within a pocket, or removed therefrom in order to allow the contents of the envelop to be inspected by the postal authorities. It is provided also with an ordinary gummed flap intended to be sealed in order to give the envelop the appearance of a sealed envelop and yet allow the same to be sent through the mail at the postage rates required for unsealed matter.

INFILLABLE BOTTLE.—A. Midso and G. Gulbrandson, New York, N. Y. This bottle is adapted to indicate if the original contents have been removed and the object of the invention is to produce a closure for a bottle or jar, which cannot be placed in its former condition after the bottle has been opened. By this means the refilling of the bottle filled with a spurious substance is prevented.

PROCESS FOR TREATING CERTAIN ORES.—H. A. Auerbach, New York, N. Y. In this instance the invention relates to the electrolytic separation of metals from their ores and admits of general use, but is of special value in connection with the production of metallic lead from galena and other plumbic ores. The method has no direct relation to any particular form of apparatus.

AERIAL VESSEL.—L. J. Suter, Jersey City, N. J. The aim in this invention is to provide a vessel or aeronef arranged to present a large sustaining surface and provided with means for conveniently causing the vessel to rise, descend and travel in the desired direction, the vessel being also capable of traveling on water or land.

CONCENTRATOR AND AMALGAMATOR.—J. I. E. Nelson, Bettles, Alaska. This apparatus is designed for the recovery of refined gold which with the foreign matter is held in suspension in a stream of water caused to drop perpendicularly into a mixer from which regulated outlet ports lead. The material to be treated contacts with quicksilver to effect the amalgamation and is forced upward again against the downward current, the purpose being to effect a thorough amalgamation with expedition.

CONCRETE DAM.—H. A. Icke, Church Stretton, Shropshire, England. The reinforced concrete dam is of cellular construction capable of compensating for expansion and contraction due to climatic changes, and open on the upstream side of the dam to form pockets for reception of water to utilize the latter to give stability to the structure and producing direct tensile instead of transverse and compression stresses, thus insuring the desired resistance and providing at the same time suitable spillways for surplus water.

WATER WHEEL.—J. L. Beil, Galena, Ill. The purpose in this improvement is to provide a water wheel adapted to be partially immersed in a stream in a horizontal position and wherein the rotor comprises a plurality of vertically movable vanes which by the movement of the rotor are moved out of and into the water.

METAL FRAME FOR GLASS PANES.—A. Busse, New York, N. Y. The intention here is to provide a frame in which no bulging or upsetting of the metal is necessary at the front of the frame to bring the flanges or heads of the bars into the same plane in order that the glass panes may bear flat against the inner faces of both the mullions and transoms.

BLOCK-MOLD.—F. May, New York, N. Y.—The inventor provides a casting mold arranged to permit of conveniently closing or opening the mold for placing the plaster material therein, and for removing the block after it has been formed and the material has set and hardened. The mold is provided with removable partitions for forming a large number of blocks simultaneously, the interior faces of the mold members being provided with registering of adjacent ribs to provide each block or slab with a continuous groove along its sides.

COMPOUND BOAT.—J. D. White, [illegible] Gardens, London, England. The main object in this case is to provide a compound boat which shall combine great stability with small displacement, and in which each of the several hulls shall have sufficient freedom to roll, pitch, and adjust its heading, so as to avoid those excessive strains which have hitherto hindered the development of boats of this type.

SMOKING PIPE.—E. B. Whitney, Oakland, Cal. Mr. Whitney's invention is specially constructed for cooling smoke, insuring deposit of nicotine therefrom, and for facilitating cleaning, when required. A comparatively long circuitous passage is provided for the smoke, so that it is cooled more than would be practicable if it had a direct passage.

Hardware.

DEVICE FOR HOLDING WIRE SCREEN.—W. A. Smitson, and A. German, Elwood, Ind. An object of the invention is to provide a device which may be located on a counter, or similarly accessible place, upon which rolls of screen of various widths and sizes may be mounted and from which the strips may be unwound as desired, measured, cut off and rolled up for immediate delivery.

SNOW SHOVEL.—G. C. Post, Ebensburg, Pa. In this invention the purpose of the improvement is to provide a strong shovel of easy and cheap construction, and with an adjustable handle, so that either edge of the shovel may be used merely by changing the position of the handle which is rotatable.

FAUCET.—A. O. Thompson, Zacapa, Guatemala. The purpose of the invention is to provide novel details of construction for a faucet which adapt it for a secure but removable attachment thereof upon the side wall of a plate metal receptacle for a removal of the contents of the receptacle from time to time as occasion may require.

NUT LOCK.—W. W. Senn, Munson Station, Pa. This invention can be used to lock the nut positively on the bolt and the locking devices can be readily adjusted to unlocked position to permit the turning of the nut on the bolt without injury thereto when desired to turn the nut farther on the bolt, or off the bolt, if so desired.

DOOR-STOP.—W. La Baw, Asbury Park, N. J. The invention has reference to door stops such as are adapted to be revolubly secured to the floor for holding the door in an open position, and each of which consists of a wedge-shaped body pivoted to the floor at its thinner end so that it can be swung into a plurality of positions.

SAFETY-GUARD FOR LOCKS AND LATCHES.—G. E. Houck, New York, N. Y. The more particular purpose here is to provide a guard having substantially the form of a plate provided with means whereby it may be fastened upon a door jamb or the like, for the purpose of preventing the bolt of the lock or latch from being forced back from the outside of the door, with the aid of a knife, screw-driver, or other instrument.

DINNER PAIL.—W. A. Edwards, Pine Bluff, Ark. An object in this case is to provide a device in which articles such as soup and coffee can be heated with very little trouble and in which the remainder of the victuals can be warmed without any danger of burning. Means provide for carrying liquid fuel for heating purposes.

SHUTTER-OPERATOR.—A. Weber, Long Branch, N. J. One object of the inventor is to so construct the device that it may be more easily applied to a window sill and casing, and a further object is to so construct the device that it will operate upon the exterior rather than the interior surface of the blind or shutter. The invention relates more particularly to that type of operator illustrated in a former patent granted to Mr. Weber.

RATCHET DRILL.—G. W. Fios, Los Angeles, Cal. The object of the improvement is to provide a device simple and serviceable in construction and inexpensive to manufacture, which is constructed to obviate the danger of the supporting point and its advancing member being unscrewed too far and thus causing an injury to the device.

PERMUTATION LOCK.—G. H. Hamilton, Portland, Ore. In view in this invention is a construction embodying a latch spindle having the customary knob and revoluble independently of the latch operating mechanism, the spindle being provided with a push bar to lock it to said mechanism, and also having a spring pawl to lock the bar in innermost and retracted positions, controlled by a permutation mechanism mounted on the spindle at the outside of and adjacent to the outer door knob.

LADDER.—J. Vaghi, Bethel, Conn. The inventor provides a ladder more especially designed for use on buildings, provides a safe escape in fire and allows firemen to quickly reach the upper stories, the ladder having its side bars formed of lazy tongs, and the rungs forming pivots on which the members of the tongs are fulcrumed, the ladder when folded taking little room, and in use is locked in extended position and spaced a sufficient distance from the face of the building to allow ascent and descent of persons.

KEY FASTENER.—P. J. Ryan, Spokane, Wash. The aim of this invention is to provide for preventing rotation of the key in the lock, from the outside of [illegible] side of the door, and in providing a device [illegible] of independent parts, which may be readily inserted or removed from the key, and which would not in any way be [illegible] by [illegible] in the points.

Heating and Lighting.

HEATER.—G. W. Bowman and J. A. [illegible], Palisades, Colo. The invention relates especially to such heaters as are used out-of-doors. The object is to produce a heater of simple construction having a [illegible] which especially facilitates a good draft and the rapid ignition of the fuel when the fire is started. It is adapted to be formed of sheet metal.

GAS-ESCAPE.—H. H. Judson, Oroville, Cal. The design is to provide an appliance for the escape of gases from gas, vapor and similar heaters, the appliance being applicable to windows of various sizes and easily set up and removed. The invention consists of an expansible window stopper, a pipe carried by and projecting outwardly from the stopper, with which the flue of the gas or oil heater connects, and a hood spaced from and covering the outer end of the pipe.

SWITCH FOR INCANDESCENT-LAMP SOCKETS.—W. A. McDonald, Grampian, Pa. Of the several objects of this invention the main is to provide a switch for an incandescent socket which may be easily operated, requiring a great deal less force to manipulate it than the ordinary key, and which can be operated by one hand without straining the suspending cord.

COMBINED VENTILATOR AND SMOKE-CONSUMER.—J. Wood, Noroton, Conn. The invention pertains to stoves and furnaces, the more particular purpose being to provide an appliance for regulating the draft, facilitating the combustion of the smoke, ventilating the room through which the smoke-pipe passes, collecting unburned cinders from the smoke and enabling these cinders to be readily ejected.

MINER'S LAMP.—J. Van Liew and A. M. Van Liew, Houghton, Mich. The lamp is adapted to burn wax, oil or other suitable fuels and the invention refers more particularly to the construction of the wick tube and burner. The device is provided with a form of combustion chamber whereby a uniform supply of air will reach the flame, thus obviating the production of smoke and other noxious gases.

Household Utilities.

CONVERTIBLE COUCH AND BED.—L. B. Jaffcott, New York, N. Y. This article can be conveniently converted from a couch into a double bed and vice versa, and when in the form of a couch the two bed sections are spaced apart to accommodate the bed sections, and when these are extended they range one along side the other to form a double bed. For this use is made of a frame on which one bed section is pivoted, and the other is adapted to be raised into an active position or lowered into a folded position.

FOLDING BED.—L. B. Jaffcott, New York, N. Y. This bed is arranged to permit of conveniently and quickly folding it longitudinally into a small space and with the bedding between the head and foot of the bed, and to allow its extension for use without danger of collapsing. For this purpose, each of the side rails is formed of bars pivotally connected with each other and with the ends at the head and foot so that the bars swing longitudinally on folding or extending the bed.

SUSPENDED CLOTHES-RACK.—B. B. Bosworth, New York, N. Y. This invention refers to elevating racks or driers adapted to support clothes or similar articles to dry. The aim is to provide a device extremely light and simple in construction, with improved means for elevating the supporting frame and for maintaining it in a horizontal position.

Machines and Mechanical Devices.

TENSION DEVICE FOR WARP-BEAMS.—G. Keller, New York, N. Y. An object of this inventor is to provide a tension device, strong and durable and which is adapted to replace the weights usually employed at the present time to keep the warp threads under tension, while at the same time utilizing the disk or drum provided upon the warp-beam in connection with the weights.

NEEDLE-CAM FOR STRAIGHT INDEPENDENT-NEEDLE KNITTING-MACHINES.—E. Popp, Couvet, Neuchâtel, Switzerland. The invention relates to knitting machines of the straight independent-needle type and more especially to the so-called locks. In the needle cam of the present invention pronounced disadvantages are overcome by preventing the needles when they are in the needle channels from an unintentional movement beyond the permissible limits.

VERTICAL ROUNDABOUT.—W. A. Sullivan, New York, N. Y. The more particular purpose in this patent is to provide a roundabout, including large boxes suspended upon a frame and adapted to turn freely and [illegible], its motive power being wholly or partially supplied by the [illegible] of passengers or of heavy passenger carriages.

SPEEDOMETER.—R. C. [illegible], [illegible], Cal. A shaft is journaled at one side of the center of gravity of the [illegible], the shaft being adapted to be [illegible] [illegible].

[illegible] is moving, it is adapted to rotate a shaft on which a governor is mounted to revolve therewith, the governor having a collar slidably mounted on the shaft which operates levers which draw tape wound on a drum mounted in the indicator wheel shaft.

MIXING-MACHINE.—W. McRae, Eastman, Ga. This invention relates to mixing machines of the rotatable box type, and the improvements are designed more particularly for a machine for the mixing of guano or commercial fertilizer. The machine comprises a rectangular box mounted for rotation about one of its diagonals as an axis, and a series of stationary paddles mounted within the box on a shaft disposed on the diagonal.

APPARATUS FOR THE CONTROL AND THE REGISTRATION OF THE OPERATIONS PERFORMED BY DISTRIBUTING MACHINES.—G. L. F. Soulage, 44 Rue de Chauny, Paris, France. The present invention has reference to a device for use in controlling and registering the operations performed by distributing-machines of all kinds and more particularly to machines for distributing railway tickets. The object of the inventor is to add up the amounts of the individual sums borne by the tickets issued.

SYNCHRONIZING APPARATUS.—P Pisani, 224 Via Cavour, Rome, Italy The object of this invention is to provide an electromechanical apparatus for synchronizing automatically the movement of a kinematograph with that of one or more talking machines. The talking machine is actuated by a source of power quite distinct from that which causes the rotation of the kinematograph, and preferably by the power derived from a clock-spring previously wound.

GLASS MOULDING MACHINE.—W J Miller, Coffeyville, Kan. In operation when the mold reaches the charging position, a gatherer places a charge in the mold, and starts the table operating mechanism. The table is at once partially rotated to bring the charge into position for pressing and the pressing operation is continued a predetermined time according as the pointer is adjusted with reference to the scale. When the piston reaches the lower end of the cylinder of the timing device, it shifts the valve controlling the forming plunger cylinder, and this plunger is raised.

BAND-SAW WHEEL.—C A. Putnam, Tupper Lake, N Y Details of construction are provided whereby the width of the faces of the pair of band-saw wheels may be decreased, to compensate for decrease in width of the saw, due to successive cutting away of the saw blade in sharpening the teeth, the saw teeth being thus projected beyond the sides of the wheels, and the band of the saw adapted for close contact with the faces of the wheels, that is essential for the rotatable movement of blade without slipping while in operation.

PULP-SHAPING MACHINE.—A Komp, New York, N Y Mr Komp finds that he is enabled by his invention to overcome some former objections by using in the place of the rubber covering of the die, a thin resilient cover, preferably of sheet metal, which is detachable with the article produced This cover gives a smooth finish, requiring no further work for its completion. Means provide for locking one of the dies successively closer to the other die after each movement of the latter, whereby the pulp may be subjected to repeated and increasing pressures.

Prime Movers and Their Accessories.

VALVE FOR ENGINES.—O Pearson, Worcester, Mass. The valve stem is mounted in a valve cage having openings for admission of gas, and outside this cage is mounted the spring for normally maintaining the valve in closed position. A rock shaft is mounted on the wall of the valve cage and one arm from this shaft engages the valve stem and the other arm is operatively connected with the spring. The spring, rock shaft and other supports are entirely outside of the valve cage and out of the path of the incoming air or gas.

Railways and Their Accessories.

COMBINED SIGNAL AND AIR-BRAKE.—A. M. Jones, Hagerstown, Md. The invention pertains to means for automatically operating the brakes and for sounding an alarm An object is to provide devices by which the brakes may be automatically set and the alarm sounded, said devices being located alongside of the track upon which the train is running.

RAILROAD SWITCH.—G D. Wesley, Texarkana, Ark. In this instance the object is to provide novel details of construction for a railroad-switch, which co-operate with a fixed frog point and pivoted wing rails therefor, so as to enable the effective control of the switch and dispense with guard rails usually used in connection with a switch of the type indicated.

LOCOMOTIVE ASH-PAN.—T. W Anderson, Fort Smith, Ark. The main purpose of this invention is to provide means whereby the pan may be dumped and in which the warping of the pan [illegible] does not necessarily interfere with the working of the dumping mechanism, [illegible] the joints are protected from heat, thus preventing the escape of fire from glowing coals, which are dropping through open joints, along a track.

[illegible].—J. S. [illegible], New York, N. Y. This invention pertains to [illegible] such as are attached at the forward end of street or trolley cars for saving persons from being run over The cradle is normally disposed in an inoperative position under the forward end of the car, but comprising a trip frame which when touched by the body, automatically releases the cradle so that it advances so as to present its forward edge under the body The motorman can directly release the cradle.

AUTOMATIC SWITCH FOR RAILWAYS.—F R. Y Torres and F S. De La P. Y Martinez, Habana, Cuba. The switch co-operates with means carried by the car, which enables the operator of the car to throw the switch to open or closed position in advance of the car In this way the car operator can advance the car on the main track or turn it into the siding or switch without leaving his platform.

Pertaining to Recreation.

ARTIFICIAL BAIT.—M A Buths, University, Va. The object here is to provide a bait, designed to resemble a small animal such as a frog, cricket or grasshopper and so constructed that the resistance of the bait as it is drawn through the water, will cause a movement of portions of the mechanism, resembling the movements of the members of the animal which the bait represents.

AMUSEMENT DEVICE.—R. H Alexander, Paterson, N J This device is of the rotary type and adapted to give simultaneously a reversing circular travel, a counter whirling rotary motion, and a billowy rocking motion. It is adapted to give a variety of circular billowy motions, calculated to please the occupants.

OPTICAL-ILLUSION APPARATUS.—E. P Hoyt, New York, N Y A mirror is employed in this device and in connection therewith, an approximately horizontal screen, so positioned relatively to the mirror that it will serve to screen one's hand while writing or drawing on a sheet of paper or pad beneath the screen, the mirror being so positioned that the reflection of the hand and the writing or drawing will be seen.

SINKER.—G W Teasdale, New York, N Y Mr Teasdale's patent relates to sinkers admitting of general use, and particularly to the type used in connection with a line for purposes of fishing. The sinker comprises a body near the ends of which are slots for use in holding a cord, and a spring winding mounted on the body and provided with portions extending into the slots for the purpose of gripping the cord therein.

BASE-BALL-GAME APPARATUS.—J W B Dean, New York N Y In this patent the inventor has reference to certain improvements in apparatus for playing a game closely analogous to the ordinary game of base ball, but played by operating dummy players mounted on a suitable support representing the field and diamond.

SOUNDING TOY.—W Bartholomae, New York, N Y This invention relates to a device for making a noise More particularly stated, it comprehends a sounding body a clapper for striking the same, and a star wheel for actuating the clapper these parts being of approved construction so as to give the complete device a maximum of efficiency

Pertaining to Vehicles.

MOTOR CYCLE.—J E. Allen, Trenton N J The inventor's intention is to provide improvements in motor cycles, whereby the main frame is spring-supported at both wheels, to reduce the shock and jar, incident to riding over rough places, to a minimum, the construction of the frame permitting the use of long and strong elliptical springs and bringing the rider's seat as low down as possible.

AUTOMOBILE-AXLE.—M D. Tindal, Columbia, S C. More especially the improvements relate to axles used in automobiles and similar motor vehicles, which permit the turning of the wheels on vertical axes in response to the movements of the steering mechanism. The vertical turning axis may be located in the plane of the wheel itself instead of being outside of the plane as common in ordinary construction

TRUCK.—C. J Ingard, San Francisco, Cal. The object in this case is to provide a truck which may be used to store lumber on board ship and other places, the truck being so constructed that by lifting one end of the load and depressing the other end the truck with its load may be swung to the desired direction in which the load is to be moved.

WHEEL.—C C Foss and C. L. White, Quitman, Ga These patentees have produced a wheel of the type in which metallic springs are arranged between the inner and outer rims. The invention resides in the special form of the springs which comprise heart-shaped bodies, the apex of which connect with one rim the other rim receiving a standard extending to the opposite end of the spring.

Designs.

DESIGN FOR A HAMMOCK.—D W Satorius, New York, N. Y The design in this case shows the hammock body ornamented by a series of grotesque images, faces, symbols, etc., which is very unique and effective.

Note.—Copies of any of these patents will be furnished by Munn & Co. for ten cents each. Please state the name of the patentee, title of the invention, and date of this paper.

Notes and Queries.

Kindly write queries on separate sheets when writing about other matters, such as patents, subscriptions books, etc. This will facilitate answering your questions. Be sure and give full name and address on every sheet.

Full hints to correspondents were printed at the head of this column in the issue of March 13th or will be sent by mail on request.

(12152) E. A. L. says Kindly explain why hot water freezes more quickly in winter time than cold water The writer set out two pans of water last winter one of boiling water and the other of hydrant water, and the boiling water froze more rapidly than the other A The only physical difference we know between water which has been boiled and water which has not been boiled is that the former has lost its dissolved air by boiling For this reason it may cool and freeze more quickly

(12153) C. K. asks In what year does the first point of Aries (I mean by that the point where the ecliptic cuts the celestial equator in spring) enter the sign of Aquarius? A We have no star map which definitely locates the eastern limit of the constellation Aquarius, so that its distance from the present location of the first point of Aries can be determined. This distance in degrees, divided by 50.2 sec., the constant of precession, will give you the time required before the first of Aries will enter the constellation Aquarius. The answer to your question as you ask it is that the first point of Aries will never enter the sign Aquarius. Each sign occupies two hours or 30 deg. on the sky and they are always in the same order moving backward together around the sky carrying the pole of the heavens around the pole of the ecliptic The astronomers at the Naval Observatory Washington, D C., will have the data you require

(12154) S F says Will you please let me know if a small wireless outfit will work satisfactorily from the top of an ordinary dwelling say 60 feet from the sidewalk? About two blocks distant in one direction is a large building twelve stories high and in the neighborhood a couple of other high buildings. A. A wireless telegraph station will work very well in the city situated as you describe. Many young men are working with their friends under these conditions The station on the top of the Waldorf-Astoria is sending many messages a day far out to sea to friends on steamers.

(12155) J H T asks Will you please explain in your notes how mathematical instrument makers fill the graduations (on a circle for instance) with the black paint and what is the black paint used? A A very good paint for filling the graduations of a rule or a thermometer is made by rubbing lampblack into shellac till the proper consistency is obtained It should be thicker than for use with a brush It is then rubbed on and in with a cloth. After the shellac has set, the excess can be taken off with a cloth wet with turpentine

(12156) G E. H says The commercial dry cell which contains the two elements a zinc rod and a carbon stick, consists of such ingredients as powdered manganese dioxide and gas carbon and ammonia chloride Now what I am anxious to know is this What chemical reactions are involved when a dry cell is in operation? What ultimate chemical changes have taken place in each ingredient when the cell is exhausted? That is to say, what new compounds have been formed in the cell? A The chemical reactions in a dry cell are the same as in any cell in which the same materials are used The manganese dioxide is changed to manganic oxide by giving off oxygen to unite with hydrogen to form water The ammonium chloride is decomposed, and the resulting products are quite complicated The ammonia is absorbed by the water till it is saturated zinc chloride is formed. Double salts of zinc and ammonium crystallize upon the zinc. An excellent chapter on dry cells is contained in Cooper's "Primary Batteries," which we can supply for $4 postpaid.

(12157) R. P D says Kindly give a process for preserving fruit for exhibition purposes. One that will not bleach shrivel or change the appearance is highly desired I have tried an aqueous solution of salicylic acid and sterilized by heat, but the color was almost removed and the skins cracked Some real estate agents want to show what can be raised in the way of fruits on irrigated lands Would not petroleum benzine do the work? A Try the following fruit or vegetables are just dropped into it (cold of course) and sealed to bear transportation Sulphurous (not sulphuric) acid, 1 part; alcohol, 1 part, water 4 parts.

(12158) L. C J says 1 Can an angle be trisected? If so, what is the rule? A. Some angles can be trisected, 90 deg for example. All angles cannot be, and there is no rule for doing it. 2. If a horse is hitched close to the load, is it easier for him to pull than if he is hitched farther from it? If so, what is the cause? A. It is a common belief that a horse can draw a load more easily when the trace is short The only reason we can see for it is that the horse tends to lift the front of the load slightly when hitched near the cart, and thus makes it easier to overcome the inequalities of the road These questions have been frequently answered in our Notes and Queries.

NEW BOOKS, ETC

The Conquest of the Air. By Alphonse Berget New York G P Putnam's Sons, 1909 8vo, 295 pp, 100 illustrations. Price, $3 50

This book is a popular work, which will serve to introduce the layman to the subject of aeronautics. It is divided into two parts the first of which deals with dirigible balloons, and the second with aeroplanes and other forms of heavier than air flying machines The book is interestingly written and while it does not go into great detail, it gives the essential facts regarding airships and aeroplanes of the past and present The first section of the book goes very thoroughly into the subject of the dirigible balloon and its history Numerous fine half tone cuts illustrate the work and there are also nearly a score of diagrams for elucidating various principles.

Aerial Navigation of To-Day By Charles C Turner Philadelphia J B Lippincott Company 1910 12mo 327 pp, 70 illustrations and diagrams. Price, $1 50

This is another popular book upon aeronautics. Besides mentioning and describing various of the leading dirigibles and aeroplanes, the author goes into the history of ballooning and of aviation The principles of mechanical flight and of aerostatics are discussed and the usefulness of flying machines and dirigibles for war and commerce is thoroughly gone over The author recognizes that a new industry has been born and discusses its effect upon society There are chapters upon aerial law, charts and landmarks, long-distance flying and lessons in flight The sensations experienced during flight and the limitations that surround it are also mentioned. The book contains an appendix of various useful tables giving the specific gravity of woods and of gases and the weights and properties of some of these woods the weights of various birds in proportion to their wing area thermometer conversion tables and Chanute's table of lift and drift There is also a glossary of aeronautic words and a table of French aeronautical terms and their meanings The book will be read with interest by the beginner in the new science of aviation

Master Painters of Britain By Gleeson White New York John Lane Company 1909 4to, 390 pp Price $3 postage 35 cents.

The sumptuous volume before us is filled with excellent reproductions in half tone of the best examples of the master painters of Britain The selection is a most admirable one British art has been both very bad and very good, and it is very easy to perpetuate the indifferent pieces Among the notable engravings which are scattered through the book we note the following which are particularly interesting "The Death of the Earl of Chatham" by John S Copley "The Death of Nelson" by Benjamin West "Stirling Castle" by Nasmyth "The Inside of a Stable" by George Morland "The Windmill" by John Crome "The Hay Wain" by John Constable Then follow reproductions of some of the works of Watts Sir Noel Paton Dante Gabriel Rossetti and Sir John Millais One of the works of the latter entitled "Chill October" shows his first great landscape which was received in 1871 with an outburst of popular appreciation and amazement that a figure painter should attempt pure landscape for in those days the idea was very strong that a man should be a specialist and not try to express himself in different branches of art. To give even the names of the other interesting pictures would be simply to give an index of the illustrations of the book There is hardly a bad selection in the whole work The engravings are admirably reproduced and the text is adequate

Tables of the Properties of Steam and Other Vapors and Temperature Entropy Table By Cecil H Peabody New York John Wiley & Sons 1909 8vo, 133 pp Price $1 net

These tables for the use of students of engineering and for engineers in general were published twenty one years ago and now that the properties of steam have been redetermined by new and refined methods they have been entirely recomputed and there has been added a temperature-entropy table especially adapted to steam turbine calculations The certainty and precision of the new determination of the properties of both saturated and superheated steam and the concordance of computation with the experimental data are such that the tables may be used with confidence and may be expected to have permanence

Outlines of Chemistry with Practical Work By Henry John Horstman Fenton First Part Cambridge England University Press New York G P Putnam Sons 8vo 367 pp Price $3

Anything which emanates from the University Press is sure to be of the highest possible scientific value The book before us intended for students who have considerable knowledge of chemistry already. The author states that the subject matter indicated in the present volume has to be covered in less than two terms by candidates for the Natural Science Tripos at Cambridge. In the two succeeding terms the work is completed along the same lines. The outlines of electrochemistry, thermal chemistry, and photochemistry are briefly introduced, and subjects such as diffusion, colloids, alloys, allotropy, and isomerism are also dealt with. The periodic classification is considered at some length, and a descriptive account of the elements and their more important compounds is incorporated with this part of the subject as far as time allows. If it should happen that the present book is found to be of assistance to students, it is the author's intention to publish this later part of the course as a second volume. From what has been said it will be seen that it is doubtful if the work will prove of a great deal of assistance as an enlarged textbook, as our methods of teaching are somewhat different from those in vogue at English universities. The book, however, is an excellent one for those who already have a considerable knowledge of chemistry.

MODERN HOMES: Selected Examples of Dwelling Houses Described and Illustrated by T. Raffles Davison. London: George Bell & Sons. New York: The Macmillan Company, 1909. 8vo.; 248 pp. Price, $5.25 net.

No one has seen more modern homes than Mr. Davison, and no one certainly knows better than he how to choose and present them to us. His architectural knowledge insures that the architecture is represented in such a manner as to satisfy the architect, while the artist in him insures that this shall not be emphasized at the expense of the general effect of his drawings. Here we have selected by one who knows some of the best and most representative modern homes. Views of exteriors and interiors, staircases, chimney corners, halls, and furniture are given, often accompanied by plans just sufficient to place them in their surroundings, and very often a sketch or two in the garden and sometimes a photograph. Drawings are accompanied by just enough letterpress to draw attention to the strong points of each design, with entire absence of any wearisome technical detail which would be out of place in such a book. The book is beautifully illustrated, and is one which we can commend to all architects.

NOTES ON PRACTICAL MECHANICAL DRAWING. Written for the Use of Students. By Victor T. Wilson, M.E., and Carlos L. McMaster, M.E. Lansing, Mich.: Published by Wilson & McMaster, 1909. 8vo.; 186 pp.

This book is a collection of notes intended to furnish the basis for a course in elementary mechanical drawing, so arranged, it is thought, that the teacher may have the widest latitude in his choice of sequence of subjects. Since the first edition two years ago the book has been rearranged with this particular point in view. It has been thoroughly revised, and also enlarged by the addition of more explanatory matter and illustrations in a [illegible]graphic section, and a chapter on dimetric and oblique drawing, and a number of chapters on working drawings and sketches. It is an excellent work.

THE ROMANCE OF MODERN CHEMISTRY. By James C. Phillips, D.Sc., Ph.D. Philadelphia: J. B. Lippincott & Co., 1909. 12mo.; 348 pp. Price, $1.50.

This book contains an [illegible] account in non-technical language of the diverse and wonderful ways in which chemical forces are at work, and of their manifold applications in modern life. Probably most people, when they think of chemistry, suppose that its fascination and its practical bearing can be appreciated only by those who have access to a well-equipped laboratory, the terms of which are [illegible] to the uninitiated. This is a mistaken view, for [illegible] was [illegible] known [illegible] the general reader [illegible] in applying the ordinary [illegible] to the [illegible]. In the present [illegible] dealt with [illegible] of the subject [illegible] from those of ordinary textbooks. The book is fascinating, and it can be read with profit by almost anyone.

TABLES AND DIAGRAMS OF THE THERMAL PROPERTIES OF SATURATED AND SUPERHEATED STEAM. By Lionel S. Marks, M.M.E., and Harvey N. Davis, Ph.D. New York: Longmans, Green & Co., 1909. 8vo.; 166 pp. Price, $1 net.

The tables of the properties of saturated steam which have up to the present time have all been based upon the classic investigations of Regnault, carried out more than sixty years ago. More recent investigations are the necessary basis for any determination of the properties of superheated steam. These investigations, it is suggested, are a careful analysis of the authors, both as to the probable errors resulting from the method of experimentation, and also as to the relation of the experimental results to the values deduced from the thermodynamic theory so far as the latter throws any light on the matter. Where the results of the separate investigations were not closely in accord, a critical estimate has been made of the relative values to be given to each in the region under consideration. This work will prove of great value to mechanical engineers.

THE METALLURGY OF THE COMMON METALS: Gold, Silver, Iron, Copper, Lead, and Zinc. By Leonard S. Austin. San Francisco: Mining and Scientific Press, 1909. 8vo.; 494 pp. Price, $4.

This is a second revised and enlarged edition, which is embellished by 195 illustrations. This book discusses principles and illustrates them from current practice. It is simple and concise. It includes the data essential to an understanding of the treatment of gold, silver, copper, iron, lead, and zinc ores. It affords a broad solid foundation to the general student of metallurgy and complete information regarding related lines of work to the specialist in any one branch. Some of the illustrations are a revelation as to the latest metallurgical processes. It shows that it is an eminently practical book.

ONE THOUSAND FORMULAS. By L. W. Marshall. Boston: The Spatula Publishing Company. 99 pp.

This compilation gives the practical working druggist full information about the making of the most common and salable preparations, as well as about many items whose formulas it would be difficult to find elsewhere. As the formulas are very recent, it would admirably supplement older receipt books.

THE GARDEN CALENDAR FOR 1910. By Ellen P. Williams. Philadelphia: Franklin Printing Company, 1909. Price, $1.

This is a wall calendar of 365 sheets, each one of which is embellished by an appropriate quotation or some practical hint for the garden. The charm of the Garden Calendar by Miss E. P. Williams is the practical advice for every day in the year, advice coming at just the time it is needed; thus on the very day you should spray your rose bushes to prevent the rust from forming it tells you to do it. If you want advice as to your pansies, your peonies, your larkspurs, your violets, your fruit trees, or even your vegetables, you will have it when you want it. You do not have to dig this advice out of a mass of other information of no immediate value. It will make an excellent holiday gift.

RULES FOR RECOVERING COAL MINES AFTER EXPLOSIONS AND FIRES. By W. F. Garforth, Mem. Inst. C.E., F.G.S. London and New York: D. Van Nostrand & Co., 1909. 18mo.; 71 pp. Price, $1.50 net.

The subject is a most important one, and has attracted great attention in this country as well as in England.

Legal Notices

60 YEARS' EXPERIENCE

PATENTS

TRADE MARKS
DESIGNS
COPYRIGHTS &C.

INVENTORS are invited to communicate with Munn & Co., 361 Broadway, New York, or 625 F Street, Washington, D. C., in regard to securing valid patent protection for their inventions. Trade-Marks and Copyrights registered. Design Patents and Foreign Patents secured.

A Free Opinion as to the probable patentability of an invention will be readily given to any inventor furnishing us with a model or sketch and a brief description of the device in question. All communications are strictly confidential. Our Hand Book on Patents will be sent free on request.

Ours is the Oldest agency for securing patents; it was established over sixty years ago.

MUNN & CO., 361 Broadway, New York
Branch Office, 625 F St., Washington, D. C.

INDEX OF INVENTIONS

For which Letters Patent of the
United States were Issued
for the Week Ending
December 14, 1909,
AND EACH BEARING THAT DATE

[See note at end of list about copies of these patents.]

Advertising apparatus, J. V. Casey	943,1[illegible]
Ae[illegible]ator, J. A. B[illegible]	943,574
Aerial navigation, J. M[illegible]	943,170
Agar agar, [illegible], A. Schmidt	943,11[illegible]
Alarm apparatus, F. I. Meyer	943,446
Alfalfa cutter, J. Jorgensen	943,808
Alloy for electrical resistance, W. B. Driver	942,008
Alloys of copper, such as brass, production of, P[illegible]k & Hodgkinson	943,159
Alumino silicate or artificial zeolite, R. Gans	943,575
Ammonia, etc., making and recovering, W. J. Dunnachie	943,760
Amusement apparatus, mechanical, W. Hastings	94[illegible]
Animal trap, N. R. Austin	942,878
Annealing flats, F. H. Daniels	943,[illegible]
Annealing flats and other shapes, F. H. Daniels	943,[illegible]
Annealing flats and other shapes, apparatus for, F. H. Daniels, 943,620	943,[illegible]
Apparel, wearing, N. J. Rotter	94[illegible]
Automobile gear, Lodge & Foster	943,240
Automobile radiators, suction for, M. Kurtzner	[illegible]
Automobile safety device, O. Kircher	[illegible]
Awning fixture, J. W. Bassett	[illegible]
Bag fastener, F. J. Brown	[illegible]
Bag fastener, C. J. Lysaght	[illegible]
Bag machine, W. Liddell	[illegible]
Baking pan, G. Mueller	[illegible]
Ball, W. W. Wrather	[illegible]
Bangles, bracelets, and the like, attachment for, B. [illegible]	943,0[illegible]
Barn construction, J. R. [illegible]	[illegible]
Battery element support, C. R. Schoenmehl	[illegible]
Battery tank storage, T. A. Willard	[illegible]
Bearing, roller, W. [illegible]	[illegible]
Bearing, roller, M. [illegible]	[illegible]
Bed bottom, J. F. McGlatchey	[illegible]
Bed, obstetrical, W. R. Peak	[illegible]
Beds, safety headboard for folding, J. M. Edmonds	943,094
Bedstead attachment, C. D. Clark	943,[illegible]
Bedstead extension, H. B. Arnold	943,170
Bell, door, F. Benzner	943,[illegible]
Belt, W. F. Lott	943,[illegible]
Berth for ships, swinging, V. Bridgman	943,[illegible]
Billiard cue tip and fastener, C. Marx	943,[illegible]
Bin. See Flour bin.	
Binder, loose leaf, McMillan & Joslyn	943,150
Binder, loose leaf, J. M. Lull	943,481
Binder, temporary, Curry & Coppage	943,036
Binding machine, C. F. Melbye	943,[illegible]
Binding, nicking machine, R. R. [illegible]	943,354
Biscuit coating machine, H. [illegible]	943,[illegible]
Blade molding means, F. Hodgkinson	943,345
Blade mounting means, J. B. Snyder	943,480
Blind slat fastener, J. B. Riley	943,380
Blowpipe, R. Odam	943,043
Boat, submarine, R. D'Equevilley Montjustin, 943,604	943,605
Boats, ship screw driving mechanism for submarine, W. Maier	943,434
Boiler cleaning device, Thomas & Thompson	942,962
Boiler flue expander, D. A. Lucas et al	943,117
Boiler tube expander, J. C. Tansey	943,879
Bolt header, J. R. Blakeslee	943,315
Book, blank, C. R. Fargo	943,[illegible]
Books and other articles, support for, G. J. Keene	943,[illegible]
Boring bar, A. F. Liden	943,088
Bottle cap, C. L. Best	943,510
Bottle closure, A. Aleison	943,221
Bottle, nonrefillable, Anderson & Ash	943,331
Bottle, nonrefillable, Birner & Heil	943,594
Bottle, nonrefillable, A. La Rose	943,495
Bowling alley, H. V. Keefer	943,419
Bowling machine, J. & J. A. Venn	942,494
Brake beam, C. F. Hinton	943,021
Brake beam hanger, R. S. Underwood	942,985
Bread, etc., machine for use in the manufacture of plain, McConnell & Wilson	943,204
Bread roll, I. B. Wood	943,596
Brick cutting machine, W. R. Hassebrock	942,541
Broiler, M. M. Dresdner	943,097
Broom bridle, C. J. Schulz	943,219
Brush holder, tooth, O. E. Jones	943,41[illegible]
Buckle, O. R. Alms	943,[illegible]
Building block, [illegible] Huts	943,518
Building construction, T. McFeely	943,447
Burglar alarm and automatic camera, combined, J. Ashe	943,282
Burglar alarm screen, I. Orance	943,[illegible]
Butter making and packaging apparatus, J. De Lisle	943,603
Cabinet for drinking cups, sanitary, L. W. Farmer	943,241
Cabinet, metallic, C. Holden	943,350
Cableway, T. S. Miller	943,062
Calculating machine, J. Brickson	943,514
Camera, moving picture, H. Meredith Jones	943,203
Can labeling machine, F. W. Wild, Jr.	942,001
Can marking machine, J. R. Coover	942,180
Can painting machine, C. Hediger	943,247
Can sealer, C. Blose	943,501
Capsule forming apparatus, H. W. Scott	943,008
Car, Lablin & Carlson	943,107
Car construction, steel, W. L. Bettendorf	94[illegible]
Car coupling, J. E. Hiller	943,070
Car coupling, J. B. & W. S. Dart	943,144
Car coupling, automatic, H. Leslie	94[illegible],116
Car door bracket, J. R. McGuire	943,030
Car door guard, W. H. Aaron	942,894
Car dumping, C. A. Lindstrom	943,259
Car fender, C. B. Albree	943,[illegible]
Car fender, J. Mylott	943,685
Car loading machine, box, A. J. Gunster	943,225
Car, steel, C. H. Anderson	943,212
Cars, strong bearing device for the ends of railway box, G. I. Weiss	943,407
Carbonating liquids, J. Bless	943,090
Carbureter, J. C. Simonsen	942,977
Carbureter, H. A. Miller	943,197
Carbureter, Ferguson & Sharpy	943,142
Card case, G. Jenner	943,[illegible]
Carpet cleaning machine for removing nap from, B. Ewald	943,613
Carpet stretcher, G. I. Neill	943,190
Carriage foot brake, C. Streibhorb	943,104
Cart, J. J. Devine	943,004
Caster retaining socket, D. A. Maxwell	943,432
Casting metallic members, H. M. Hager	943,928
Casting operations, means for preparing bars for the, M. H. Fletcher	943,303
Cement surfaces and product, treating Portland, M. Toch	943,[illegible]
Centering machine, W. F. Ruth	943,467
Centrifugal regulator, W. Jahns	943,600
Chandelier, L. B. Hornbeck	943,148
Chart, adjustable, F. D. Webster	943,150
Check, combination fluid and vacuum, H. T. Case	94[illegible],887
Chick separator, H. Hill	942,902
Chocolate composition containing heating and storage system for, C. J. Dion	943,[illegible]
Chuck, L. W. Hub	943,616
Chuck and tool holder, reversing, M. N. Jarvis	943,414
Churn, F. Peter	943,200
[illegible], J. J. Walsh	941,590
Clock, eight-day alarm, P. I. [illegible]	943,812
Clothes line support, window, T. A. MacDonald	943,473
Clothespin, J. F. Norman	942,71[illegible]
Clot[illegible], T. White	943,2[illegible]
C[illegible] angle, W. D. Kendrick	94[illegible]
Cock, blow off, J. B. Youngblood	94[illegible]
Coffee pot, C. F. Blanke	943,313
Coffee roasting, B. & G. De Mattia	943,278
Coin paying machine, C. Menchen	943,0[illegible]

Concrete
Reinforced Concrete
—AND—
Concrete Building Blocks

Scientific American Supplement 1543 contains an article on Concrete, by Brysson Cunningham. The article clearly describes the proper composition and mixture of concrete and gives results of elaborate tests.

Scientific American Supplement 1538 gives the proportion of gravel and sand to be used in concrete

Scientific American Supplements 1567, 1568, 1569, 1570, and 1571 contain an elaborate discussion by Lieut. Henry J Jones of the various systems of reinforcing concrete concrete construction, and their applications. These articles constitute a splendid text book on the subject of reinforced concrete. Nothing better has been published.

Scientific American Supplement 997 contains an article by Spencer Newberry in which practical notes on the proper preparation of concrete are given.

Scientific American Supplements 1568 and 1569 present a helpful account of the making of concrete blocks by Spencer Newberry

Scientific American Supplement 1534 gives a critical review of the engineering value of reinforced concrete.

Scientific American Supplements 1547 and 1548 give a resume in which the various systems of reinforced concrete construction are discussed and illustrated.

Scientific American Supplement 1564 contains an article by Lewis A Hicks, in which the merits and defects of reinforced concrete are analyzed.

Scientific American Supplement 1551 contains the principles of reinforced concrete with some practical illustrations by Walter Loring Webb.

Scientific American Supplement 1573 contains an article by Louis H Gibson on the principles of success in concrete block manufacture, illustrated.

Scientific American Supplement 1574 discusses steel for reinforced concrete.

Scientific American Supplements 1575, 1576, and 1577 contain a paper by Philip L. Wormley Jr., on cement mortar and concrete, their preparation and use for farm purposes. The paper exhaustively discusses the making of mortar and concrete, depositing of concrete, facing concrete, wood forms, concrete sidewalks, details of construction of reinforced concrete posts.

Each number of the Supplement costs 10 cents.

A set of papers containing all the articles above mentioned will be mailed for $1.80.

PHOTOGRAPHING A STAR SPECTRUM.

(Continued from page 485.)

of Lake Geneva, the summer home of many of the Windy City's millionaires. On high ground to the north of the lake, the observatory presents a fine appearance with its great dome to the west and two smaller domes to the east of the buildings. Passing through the main doors, one enters a fine rotunda, and going up a flight of marble steps comes into the great dome, 90 feet in diameter and gazes on the great telescope towering aloft. One beholds a massive iron stand supporting an immense steel tube of boiler plate sixty two feet in length, five feet in diameter at the middle, tapering to three and a half feet at either end At the upper end of the tube is the object glass, with a clear aperture of forty inches, at the other end the eyepiece and micrometer, for viewing and measuring the planets and stars, or these may be replaced by a camera attachment for photography, or by a spectrograph for obtaining the spectra of stars planets, or sun The telescope tube is so long that the eye end is about thirty feet higher when an object is viewed near the horizon, than when looking at a star directly overhead. To use such a telescope, requiring as it would a long system of ladders, would be well nigh impossible, were it not for an invention of Sir Howard Grubb in making the whole observing floor an elevator The front page illustration shows the floor at its lowest point, while another view shows the floor raised as high as possible At Yerkes the floor, seventy five feet in diameter, big enough to seat six hundred people, can be raised and lowered through a distance of twenty three feet, and thus the observer when working with the telescope may keep the floor at a convenient distance below the end of the telescope, the operating power being electricity In the front page illustration are shown two of the four counterweights that balance the floor An idea of the size will be obtained by remembering that the dome is ninety feet in diameter When the astronomer wishes to observe a particular star, it is necessary to turn the slit of the dome in the direction of the star, and hence the dome must be revolved This is ninety feet in diameter and weighs one hundred and forty tons, but again by the aid of electric motors it can be rotated at will by turning on the electric current from the rising floor

Turning to the telescope we find a machine of fifty-three tons in weight, wherein the movable parts weigh twenty tons. This weight the astronomer has to put in motion when he turns the telescope, yet ball bearings and the refinements of modern engineering permit him to move the great machine, using only his own physical strength For quickly turning the telescope, electric motors are used The telescope is set up by what is known technically as the equatorial mounting, one axis, the polar axis, in the meridian parallel to the earth's axis of rotation, the other, the declination axis, at right angles to it. Circles on these two axes give the astronomer the means of locating the star by its hour angle and declination When the star is once in the field of the telescope, it is kept there by a clockwork mechanism driving the telescope about the polar axis at a speed exactly equal and opposite to the earth's rotation. The writer of this article has used the telescope when the thermometer stood at 26 deg below zero Fahrenheit, and yet at this temperature the mechanism worked to perfection, which speaks wonders for the excellence of this mounting made by the well-known firm of Warner & Swasey Indeed the professional astronomer has a hard life of it, which requires a great amount of physical endurance. In the summer nights when the temperature renders life comfortable, the nights are short, the astronomer might then be permitted to join a labor union; for he can

(Concluded on page 496.)

Important Books

Industrial Alcohol
ITS MANUFACTURE AND USES
A Practical Treatise based on Dr MAX MAERCKER'S "Introduction to Distillation" as revised by Drs. DELBRUCK and LANGE. Comprising Raw Materials, Malting, Mashing and Yeast Preparation, Fermentation Distillation, Rectification and Purification of Alcohol, Alcoholometry the Value and Significance of a Tax-Free Alcohol, Methods of Denaturing, Its Utilization for Light, Heat and Power Production, a Statistical Review and the United States Law
By JOHN K. BRACHVOGEL, M.E.
528 Pages 105 Illustrations Price $4.00

Experimental Science
By GEORGE M. HOPKINS
Revised and Greatly Enlarged. 2 Octavo Volumes. 1,100 Pages. 900 Illustrations Cloth Bound. Postpaid. $5 00
Owing to the amount of new matter added the book is now published in two volumes, handsomely bound in buckram. Of the additions which have been made, among the most important are: A full illustrated description of ⅙ H. P Electric Motor, prepared expressly for this edition of "Experimental Science"; chapters on Alternating-current Machinery, and clear concise Explanations of Wireless Telegraphy and Telephony Electrical Measuring Instruments, the Electric Clock the Telegraphone, High Tension Currents, the Nernst Lamp and methods of measuring the heat of the stars No other work contains such a fund of trustworthy up-to-date scientific information presented in a clear and simple style. Send for descriptive circular

The Scientific American Cyclopedia of Receipts, Notes and Queries
15,000 RECEIPTS 734 PAGES
Price $5.00 in cloth
This splendid work contains a careful compilation of the most useful Receipts and Replies given in the Notes and Queries of correspondents as published in the SCIENTIFIC AMERICAN during the past sixty years together with many valuable and important additions.
Over Fifteen Thousand selected receipts are here collected, nearly every branch of the useful arts being represented It is by far the most comprehensive volume of the kind ever placed before the public.

Modern Plumbing Illustrated
By R. M STARBUCK
Price $4 00
A COMPREHENSIVE and up-to-date work illustrating and describing the Drainage and Ventilation of Dwellings Apartments, and Public Buildings, etc. The very latest and most approved methods in all branches of sanitary installation are given Adopted by the United States Government in its sanitary work in Cuba Porto Rico and the Philippines, and by the principal boards of health of the United States and Canada. 300 pages; 55 full page illustrations.

Modern American Lathe Practice
By OSCAR E PERRIGO, M.E.
Price $2.50
A COMPLETE book of 400 pages on The Modern American Lathe Its development from the earliest times up to the present day Its modern form as constructed by up-to-date builders; its general and special classes of work; the quantity of its output and its marvelous accuracy

Modern Steam Engineering
in Theory and Practice
By GARDNER D HISCOX, M E.
Price $3 00
THIS is a complete and practical work of 487 pages, dealing with the care and management of Boilers, Engines, Pumps, Superheated Steam, Refrigerating Machinery, Dynamos, Motors, Elevators, Air-Compressors, and all other branches with which the modern Engineer must be familiar
Nearly Two Hundred Questions with their Answers on Steam and Electrical Engineering likely to be asked by the Examining Board are included These if studied by you will help you to procure a license. It is fully illustrated with detail engravings, not to be found elsewhere

Punches, Dies and Tools for Manufacturing in Presses
By JOSEPH V WOODWORTH
Price $4 00
A PRACTICAL work of 500 pages fully illustrated by nearly 700 engravings, being an encyclopedia of Die Making, Punch Making, Die Sinking, Sheet Metal Working, and Making of Special Tools, Sub-Presses, Devices and Mechanical Combinations for Punching, Cutting, Bending, Forming, Piercing, Drawing, Compressing and Assembling Sheet Metal Parts, and also Articles of other Materials in Machine Tools. Two Hundred and Ten Processes are clearly described and fully illustrated.

☞ A special circular describing these books sent on request.

☞ Any of these books sent prepaid on receipt of price.

Classified Advertisements

Advertising in this column is 75 cents a line. No less than four nor more than 12 lines accepted. Count seven words to the line. All orders must be accompanied by a remittance. Further information sent on request.

READ THIS COLUMN CAREFULLY.—You will find inquiries for certain classes of articles numbered in consecutive order. If you manufacture these goods write us at once and we will send you the name and address of the party desiring the information. There is no charge for this service. In every case it is necessary to give the number of the inquiry. Where manufacturers do not respond promptly the inquiry may be repeated.

MUNN & CO., Inc.

BUSINESS OPPORTUNITIES.

LOCAL REPRESENTATIVE WANTED.—Splendid income assured right man to act as our representative after learning our business thoroughly by mail. Former experience unnecessary. All we require is honesty, ability, ambition and willingness to learn a lucrative business. No soliciting or traveling. This is an exceptional opportunity for a man in your section to get into a big paying business without capital and become independent for life. Write at once for full particulars. Address E. R. Marden, Pres., The Nat'l Co-op. Real Estate Co., Suite 322, Marden Bldg., Washington, D. C.

Inquiry No. 9018.—For manufacturers of "Wydt's Electro-Catalytic Sparking Plug."

ITALY.—Important technical office, having widest connection in Italy is prepared to treat with a first-class Machine-manufacturing firm. For full information and particulars, write to Ing. Michele S. Fox, Turin (Italy), Corso Oporto Bibis.

Inquiry No. 9029.—Wanted the manufacturers of the Van Winkle Woods & Sons, and the Weber power motors.

EDUCATIONAL.

CIVIL SERVICE EMPLOYEES are paid well for easy work; examinations of all kinds soon; expert advice, sample questions and Booklet 40 describing positions and telling easiest and quickest way to secure them free. Washington Civil Service School, Washington, D. C.

Inquiry No. 9000.—For information regarding shoes not made of leather but similar to the same and are as durable.

PATENTS FOR SALE.

PATENT FOR SALE.—Something New Automobile Automatic Drop Brake. For further particulars, address Box 45, W. Enfield, Maine.

Inquiry No. 8996.—Wanted addresses of manufacturers of machinery for working orange wood manicure sticks.

FOR SALE.—States' rights or outright, Patent 907,801 for Safety Gas Hose Connection. Instantly and absolutely seals hose on detachment from stove. Can't suicide by Safety Hose. Dennis Tanguey, 718 So. 6th St., Philadelphia, Pa.

Inquiry No. 9014.—For manufacturers of machinery, supplies, etc., to equip a small plant for the manufacture of iridium-tipped gold nib making for fountain pens.

FOR SALE

FOR SALE.—Engine lathe, swings 8½ in., takes 26 in. between centers. Complete with full set change gears to cut all pipe threads 3 to 40 in. Price only $40.00. Address L. F. Grammes & Sons, Allentown, Pa.

Inquiry No. 9016.—Wanted, machinery necessary for an installation of a plant for refining salt by a modification of the Bessemer process.

WANTED

WANTED TO BUY Water Cooled Stationary Gasoline Engines, from 1 to 10 h. p. from manufacturers of same willing to furnish under our own name in carload lots, or large quantities, for cash. Manufacturers state full particulars to Water Works, Box 773, New York.

Inquiry No. 9043.—Wanted to buy silk machines from re-reeling, twisting, doubling, to the final process of making it into clothes.

LISTS OF MANUFACTURERS.

COMPLETE LISTS of manufacturers in all lines supplied at short notice at moderate rates. Small and special lists compiled to order at various prices. Estimates should be obtained in advance. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9025.—Wanted, address of rubber manufacturers in Germany.

A LIST OF 1,500 mining and consulting engineers on cards. A very valuable list for circularizing, etc. Price $15.00. Address Munn & Co., Inc., List Department, Box 773, New York.

Inquiry No. 9030.—Wanted, catalogues and all information on machinery for braiding straw in manufacturing straw hats.

Inquiry No. 9034.—For manufacturers of machinery that could reduce stumps to kindling wood.

Inquiry No. 9036.—Wanted, the address of the manufacturers of "Cycle Ball Bearing Suspenders."

Inquiry No. 9038.—Wanted, the address of the Chipman Electric Purifying Co.

Inquiry No. 9042.—Wanted the address of Farney Safety Razor Co.

Inquiry No. 9044.—Wanted to buy outfits necessary for agate polishing.

Inquiry No. 9046.—Wanted, machinery used for the manufacture of all kinds of fruit boxes, baskets and crates.

Inquiry No. 9048.—Wanted, address of manufacturers of metal table slides for extension tables.

Inquiry No. 9049.—Wanted to buy rotary brushes suitable for a shoe shining machine.

Inquiry No. 9052.—Wanted to buy machinery, etc., for a beer plant, that manufactures beer by means of glucose.

Inquiry No. 9053.—Wanted, address of firms who install plants to manufacture nitrogen.

Inquiry No. 9054.—Wanted address of manufacturers of articles made from mica.

Inquiry No. 9055.—Wanted address of parties interested in Log Cleaning Machines.

Inquiry No. 9056.—For manufacturers of window shades.

Inquiry No. 9057.—For manufacturers of glass and china balls, used as fixtures or ornaments on lightning rod equipment, also weather vanes for same purpose.

Inquiry No. 9058.—Wanted firms who make machinery used for pulverizing soap-stone.

Inquiry No. 9059.—For manufacturers of flexible steel sheet [illegible].

FLY PAPERS. - FORMULAS FOR sticky fly Papers are contained in SCIENTIFIC AMERICAN SUPPLEMENT Nos. 1057 and 1324. Each issue [illegible]. Price 10 cents each, from this office, and from all newsdealers.

(Concluded from page 486.)

work but eight hours. But he would be obliged to resign from the union in the winter time, for observing starts at five in the evening and continues till seven the next morning, fourteen hours without a break. And how pleasant this is with the thermometer twenty-six degrees below zero! It needs quite a deal of enthusiasm to keep one from freezing to death!

To photograph the spectrum of a star, a spectroscope or rather spectrograph is attached to the eye end of the telescope. The object glass focuses the star's light on a fine slip not more than one hundredth of an inch in width and one-eighth of an inch in length. After the light passes through this slit it passes through the collimating telescope, then through the prism or prisms which break the star's light up into its component colors or spectrum, then through the camera lens and is finally brought to a focus on the photographic plate where is obtained a photograph of the star's spectrum. Much careful thought and many refinements were necessary before the spectroscope was brought to its present great degree of precision. To mention a few of them. How is it possible to keep the great telescope tube so accurately directed to the star that its light is focused on the center of the slit one-hundredth of an inch wide, for if the light does not pass through the slit it will not fall on the photographic plate. This was made possible by making the slit jaws of polished silver, and watching the stray light reflected from the silver jaws by combining prisms and lenses in a rather curious fashion. The observer keeps his eye at an eyepiece where he can see the star image on the slit, and causes the star image to remain centered there by using the slow motions of the telescope. The exposure necessary to make a photograph depends on the brightness of the star and may last from a few minutes to two, three, or five hours, or in some few cases to eight or ten hours. During this long exposure the temperature has probably fallen a number of degrees, and the instrument has been affected by all its parts contracting. This might result in a change in the prisms with the consequence that the photographed spectrum will not be sharp and in as good definition as it might be. To overcome these difficulties, the whole spectrograph was inclosed in a tight aluminium case lined with glass work so as to be non-conducting. Fine wires were placed inside this case. While the exposure was being made a thermometer inside the case was watched through a glass window, and if the temperature dropped, a current of electricity was turned through the wires inside the case, and kept turned on till the proper temperature was reached. Within the past year a thermostat has been introduced and the temperature is automatically kept constant. And hence while the exposure is being made the spectrograph is kept at a constant temperature, there is no change in its several parts and a sharply-defined spectrum will result. A wonderfully accurate instrument this makes leading to results of the highest degree of precision.

AN AERIAL PASSENGER RAILWAY.

(Continued from page 488.)

haulage. From the haulage cable, which is one and one-half inches in diameter, the buckets are suspended, their entire weight being sustained by two steel four-inch flanged wheels running over the stationary cable.

These buckets are constructed of heavy wrought iron, six feet long and four wide, with a door opening on the right side, which door is securely bolted when the bucket is en route. There are twenty-six buckets on the line, carried by the haul-

(Concluded on page 499.)

Aeroplanes and Motors

We are building aeroplanes of the [illegible] type. [illegible]

  [illegible]

(Concluded from page 486.)

[illegible] cable, spaced at equal distances of [illegible] feet apart. These buckets are held to the runners by a one-half by two-inch steel frame, allowing it to swing freely on an axle between the flanged wheels. The seating capacity of each bucket is four.

In the entire distance there are fifty towers, built of eight by eight timbers, most of which were cut within a mile of the road. Over these towers run the cables. The stationary cable is the higher one, the haulage cable being two feet below and carried midway in the frame that supports the buckets. This haulage cable is endless, winding about a huge drum at either terminal. The towers are not placed an equal distance apart, but according to the slope and the contour of the ground. On the longer stretches they are frequently two hundred feet between, while at the base and summit they are within a few feet of one another. Perhaps the best example of the entire simple working plan may be found in the large stores of a city, where package carriers are in use. The little wire baskets that carry your purchases from the clerk to the wrapper are in miniature duplicates of these huge man-carrying buckets, save where the former are operated by springs, the latter are moved by electric power.

The entire distance covered, from base to summit, is one and one-half miles, and in traveling this you are raised from nine thousand feet at Silver Plume to something greater than twelve thousand five hundred feet at the summit. This is, approximately, one foot lift for every two feet covered. In order to attain the same elevation, any road in the world—Pike's Peak cog road a possible exception—would have to traverse several times the distance. The time is thirty minutes each way.

The motive power is electric, the current being transmitted from Georgetown, four miles distant. Two motors are used, both of thirty-five horse-power each, and both located at the upper terminal. One motor is sufficient to operate the endless cables on an average haul, but on other occasions, where the buckets are filled, both are thrown in.

The entire road is equipped with electric signals and telephones. In its length are five stations, built about the towers, each with its watchman. The slightest accident is promptly telephoned to the engineer, and the buckets stopped.

The plans were first drawn up late in 1905, and the construction commenced the year following. It was not until the summer of 1908, however, that the road was in full running order. The total cost was slightly in excess of $70,000.

◆

A MACHINE FOR SIMULTANEOUSLY FIRING MANY BLASTS.

(Concluded from page 484.)

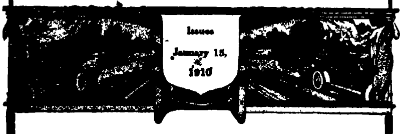
by the shaft. When the switch is thrown to the lower contact, the fuse circuit receives the whole current from the electric generator.

All of the fuses are melted instantly by the heavy rush of current accentuated by the inductive kick of the coil, thus producing a simultaneous firing of all the charges of explosives used. In deepening the river at Sault Ste. Marie for the United States government, the contracting firm used three similar machines, but larger and more powerful, operated by compressed-air engines. These machines were perfectly automatic and unfailing in operation. In all cases the fuses were arranged in parallel circuit between the two mains of the dynamos, the pressure being 12 volts. It is stated that these devices operated so simply that it required only the opening of an air valve to fire three hundred charges of dynamite at one time.

◆

[illegible].—A preparation for greasing wool, according to a French patent, is made by the saponification of mixtures of mineral oils and vegetable oils by alkaline carbonates.

THE AUTOMOBILE NUMBER of the SCIENTIFIC AMERICAN



THIS year bigger and even better than it ever was. It has been our purpose in publishing this annual review to give the automobile owner and the prospective purchaser truly helpful information, and to that end the number will contain the following articles:

1 The Automobile and the Farmer

2 How to Overhaul Your Car

3 The Automobile Fire Engine

All the latest automobile pumping engines, chemical cars, hook and ladder trucks, and hose carts are described

4. The Automobile and the Road

The automobile has presented to the road engineer new problems for solution. He must render his roads impervious to water and practically proof against the destructive effect of tires. The United States Government through the Office of Public Road Inquiry is now studying this subject. The article written by Mr Page, Director of the Office of Public Roads, describes what has been done

5. Anti "Joy Ride" Devices.

This article is a complete description of devices which have been invented for the purpose of preventing chauffeurs from taking out their owners' machines.

6 The Modern Electric Automobile

7 Making Your Own Repairs.

8 The Cars of 1910

9 Automobile Identification Chart

Sometimes you have wondered what make of car was that which skimmed past your admiring eyes. The 1910 Automobile Number will enable you to identify any car by its radiator and engine bonnet. About thirty-five automobiles are thus illustrated for identification in a sketchy, artistic way

10 The Inexpensive Car

Any man with a good salary can now afford to own some kind of an automobile. How the machines are constructed and what may be expected of them is lucidly set forth.

11 The Wonderful Rise of the Automobile Industry

12 Automobile Novelties.

Order from your newsdealer or from

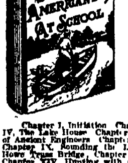
The Scientific American Boy at School

By A. RUSSELL BOND

12mo. 338 Pages. 314 Illustrations.
Price $2.00 postpaid.



SCIENTIFIC AMERICAN BOY AT SCHOOL

THIS book is a sequel to The Scientific American Boy, many thousand copies of which have been sold and has proven very popular with the boys. The main object of the book is to instruct how to build various devices and apparatus, particularly for outdoor use. The construction of the apparatus which is fully within the scope of the average boy is fully described and the instructions are interwoven in an interesting story, a feature which has assisted in making the Scientific American Boy so popular with the boys.

It takes up the story of "Bill" and several of his companions at boarding school. They form a mysterious Egyptian society whose object is to emulate the resourcefulness of the ancients. Their Chief Astrologer and Priest of the Sacred Scarabæus is gifted with unusual powers, but his magic is explained so that others can copy it. Under the directions of the Chief Engineer dams, bridges, and canal locks are constructed. The Chief Admiral and Naval Constructor builds many types of boats, some of which are entirely new. The Chief Craftsman and the Chief Artist also have their parts in the work done by the Society, over which Pharaoh and his Grand Vizier have charge. Following is a list of the chapters:

Chapter I, Initiation; Chapter II, Building a Dam; Chapter III, The Skiff; Chapter IV, The Lake House; Chapter V, A Midnight Surprise; Chapter VI, The Modern Order of Ancient Engineers; Chapter VII, A "Pedal Paddle Boat"; Chapter VIII, Surveying; Chapter IX, Sounding the Lake; Chapter X, Signalling Systems; Chapter XI, The Howe Truss Bridge; Chapter XII, The Seismograph; Chapter XIII, The Canal Lock; Chapter XIV, Hunting with a Camera; Chapter XV, The Gliding Machine; Chapter XVI, Camping Ideas; Chapter XVII, The Haunted House; Chapter XVIII, Sun Dials and Clepsydras; Chapter XIX, The Fish Tail Boat; Chapter XX, Kite Photography; Chapter XXI, Water Kites and Current Sailing; Chapter XXII, The Wooden Canoe; Chapter XXIII, The Bicycle Sled; Chapter XXIV, Magic; Chapter XXV, The Sailboat; Chapter XXVI, Water Sports, and Chapter XXVII, A Geyser Fountain. Index.

PREPARED ASBESTOS FIBRE for Manufacturers use

R. H. MARTIN,
OFFICE ST PAUL BUILDING
220 B'way, New York.

There are 112 parts of the Cadillac "Thirty" which are accurate to the one-thousandth of an inch

This means that in these 112 parts there is not a variation to exceed one-half the thickness of a hair.

In the assembling of the motors and other essentially accurate parts, the use of files or even emery cloth is not permitted. It is not required.

This is because Cadillac cars are standardized in every detail.

Every part fits exactly in its place. Every part works in perfect harmony with every other part.

It is this thorough standardization that gives the Cadillac that smooth velvety noiseless action.

It is this thorough standardization that almost eliminates friction.

It is this thorough standardization that enables the Cadillac motor to develop more power than any motor of its size ever built.

It is this thorough standardization which enables a greater proportion of the motor's power to be delivered to the ground than in any other car the world has ever produced.

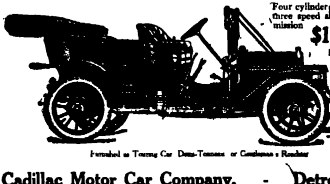
It is this thorough standardization which eliminates the twisting, grinding, racking wear characteristic of the car with ill-fitting parts and connections.

It is this thorough standardization which has caused the Cadillac to be universally recognized as the most durable and longest lived car ever made.

It is this thorough standardization which has eliminated the causes of many of the most vexatious "automobile troubles."

It is this thorough standardization that is back of the Cadillac reputation for being the most economical motor car to operate and maintain.

And lastly there is no motor car at any price, so thoroughly standardized as is the Cadillac.



Four cylinder; 30 horse power; three speed sliding gear transmission

$1600 (F. O. B. Detroit)

Including the following equipment:—Magneto, four unit coil with dry cells, one pair gas lamps and generator, one pair side oil lamps, one tail lamp, horn, set of tools, pump and tire repair kit, robe rail, tire irons.

Furnished as Touring Car, Demi-Tonneau or Gentleman's Roadster

Cadillac Motor Car Company, - Detroit, Mich.
